AboutCode

AboutCode Authors

Sep 28, 2021

CONTENTS

Welcome to the AboutCode documentation.

This set of documents provides an overview of the AboutCode Projects sponsored by AboutCode.org (https://www.aboutcode.org), as well as references to the various GitHub project sites that maintain the actual projects and their documentation.

All community contributions are welcome.

CHAPTER

ONE

ABOUTCODE ORGANIZATION DOCS

1.1 Contributing

The AboutCode organization welcomes you and your interest in contributing to our organization. We are always looking for enthusiatic contributors and we are willing to lend a helping hand if you have any questions or comments. That being said, here a few resources to help you get started.

1) **Take a look through our public repos here: https://github.com/nexB/**
    - Find one you are interested in and check out its open **Issues**
2) **If you have specific questions browse through our documentation here: https://aboutcode.readthedocs.io/en/latest/**
    - Depending on the project, there may be a seperate ReadTheDocs website
    - If you did not find what you were looking for or you still have questions, open an issue on the relevant repository, or ask directly via Gitter

You can always interact with the AboutCode organization and our extended community on Gitter

1.1.1 Contribution Guidelines:

Writing good Commit Messages

What is good commit message? We want to avoid this: https://xkcd.com/1296/

Read these articles:

- by @cbeams How to Write a Git Commit Message
- this README from Linus Torvalds https://github.com/torvalds/subsurface-for-dirk/blob/0f58510ce0244513521296b75281fcc32f72a931/README#L73
- from the Git book: https://git-scm.com/book/en/v2/Distributed-Git-Contributing-to-a-Project

The main style points are these:

Subject:

- Add a issue number at the end of the line when available as in "#234"
- Limit the subject line to 50 characters
- Capitalize the subject line
- Do not end the subject line with a period
- Use the imperative mood in the subject line: you are giving orders to the codebase

Body:

- Separate subject from body with a blank line
- Wrap the body at 72 characters. Use only spaces for formatting, not tabs.
- Use the body to explain what and why vs. how
- use bullets with a * if needed
- Add a Reported-by: if needed
- End your message with a Signed-off-by: prefixed by a blank line

Other comments:

We like to suffix the subject line with an issue number. If this was a trivial change it may not have one though. If it had one a you would use `#156` as a suffix to the first line.

We like to tell why the commit is there and use an imperative style, like if you were giving an order to the codebase with your commit:

e.g rather than : `Minor fix for unnecessary operations.` may be `Remove unnecessary operations #123` or:

```
Remove unnecessary operations #123

    * If the ts timestamp does not exist, do not compare with old one.
```

You need to add a signoff to your commit. So the final message would have looked like this:

```
Remove unnecessary operations #123

    * If the ts timestamp does not exist, do not compare with old one.

Signed-off-by: Philippe Ombredanne <pombredanne@nexb.com>
```

Testing

ToDo

We need to create this content.

1.2 Documentation Guidelines

1.2.1 Document Software Setup

AboutCode documentation is built using Sphinx. See http://www.sphinx-doc.org/en/master/index.html

AboutCode documentation is distributed using "Read the Docs". See https://readthedocs.org/

Individual document files are in reStructuredText format. See http://www.sphinx-doc.org/en/master/usage/restructuredtext/basics.html

You create, build, and preview AboutCode documentation on your local machine.

You commit your updates to the AboutCode repository on GitHub, which triggers an automatic rebuild of https://aboutcode.readthedocs.io/en/latest/index.html

1.2.2 Clone AboutCode

To get started, create or identify a working directory on your local machine.

Open that directory and execute the following command in a terminal session:

```
git clone https://github.com/nexB/aboutcode.git
```

That will create an /aboutcode directory in your working directory. Now you can install the dependencies in a virtualenv:

```
cd aboutcode
virtualenv -p /usr/bin/python3.6 docs-venv
source docs-venv/bin/activate
```

Now, the following prerequisites are installed

- Sphinx
- sphinx_rtd_theme (the format theme used by ReadTheDocs)
- docs8 (style linter)

```
pip install Sphinx sphinx_rtd_theme doc8
```

Now you can build the HTML documents locally:

```
cd docs
make html
```

Assuming that your Sphinx installation was successful, Sphinx should build a local instance of the documentation .html files:

```
open build/html/index.html
```

In case this command did not work, for example on Ubuntu 18.04 you may get a message like "Couldn't get a file descriptor referring to the console", try:

```
see build/html/index.html
```

You now have a local build of the AboutCode documents.

1.2.3 Improve AboutCode Documents

Before you begin creating and modifying AboutCode documents, be sure that you understand the basics of reStructuredText as explained at http://www.sphinx-doc.org/en/master/usage/restructuredtext/basics.html

Ensure that you have the latest AboutCode files:

```
git pull
git status
```

Use your favorite text editor to create and modify .rst files to make your documentation improvements.

Review your work:

```
cd docs
make html
open build/html/index.html
```

AboutCode uses Travis-CI to test build status and check links, so run this script at your local system before creating a Pull Request.

```
cd docs
./scripts/sphinx_build_link_check.sh
./scripts/doc8_style_check.sh
```

1.2.4 Share AboutCode Document Improvements

Follow standard git procedures to upload your new and modified files. The following commands are examples:

```
git status
git add source/index.rst
git add source/how-to-scan.rst
git status
git commit -m "New how-to document that explains how to scan"
git status
git push
git status
```

The AboutCode webhook with ReadTheDocs should rebuild the documentation after your Pull Request is Merged.

Refer the Pro Git Book available online for Git tutorials covering more complex topics on Branching, Merging, Rebasing etc.

1.2.5 Continuous Integration

The documentations are checked on every new commit through Travis-CI, so that common errors are avoided and documentation standards are enforced. Travis-CI presently checks for these 3 aspects of the documentation :

1. Successful Builds (By using `sphinx-build`)
2. No Broken Links (By Using `link-check`)
3. Linting Errors (By Using `Doc8`)

So run these scripts at your local system before creating a Pull Request:

```
cd docs
./scripts/sphinx_build_link_check.sh
./scripts/doc8_style_check.sh
```

1.2.6 Style Checks Using `Doc8`

How To Run Style Tests

In the project root, run the following command:

```
$ doc8 --max-line-length 100 docs/source/ --ignore D000
```

A sample output is:

```
Scanning...
Validating...
docs/source/scancode-toolkit/misc/licence_policy_plugin.rst:37: D002 Trailing␣
↪whitespace
docs/source/scancode-toolkit/misc/faq.rst:45: D003 Tabulation used for indentation
docs/source/scancode-toolkit/misc/faq.rst:9: D001 Line too long
docs/source/scancode-toolkit/misc/support.rst:6: D005 No newline at end of file
========
Total files scanned = 34
Total files ignored = 0
Total accumulated errors = 326
Detailed error counts:
    - CheckCarriageReturn = 0
    - CheckIndentationNoTab = 75
    - CheckMaxLineLength = 190
    - CheckNewlineEndOfFile = 13
    - CheckTrailingWhitespace = 47
    - CheckValidity = 1
```

Now fix the errors and run again till there isn't any style error in the documentation.

What is Checked?

PyCQA is an Organization for code quality tools (and plugins) for the Python programming language. Doc8 is a sub-project of the same Organization. Refer this README for more details.

What is checked:

- invalid rst format - D000
- lines should not be longer than 100 characters - D001
  - RST exception: line with no whitespace except in the beginning
  - RST exception: lines with http or https URLs
  - RST exception: literal blocks
  - RST exception: rst target directives
- no trailing whitespace - D002
- no tabulation for indentation - D003
- no carriage returns (use UNIX newlines) - D004
- no newline at end of file - D005

1.2.7 Intersphinx

Aboutcode documentation uses Intersphinx to create links to other Sphinx Documentations, to maintain links to other Aboutcode Projects.

To link sections in the same documentation, standart reST labels are used. Refer Cross-Referencing for more information.

For example:

```
.. _my-reference-label:

Section to cross-reference
--------------------------

This is the text of the section.

It refers to the section itself, see :ref:`my-reference-label`.
```

Now, using Intersphinx, you can create these labels in one Sphinx Documentation and then referance these labels from another Sphinx Documentation, hosted in different locations.

You just have to add the following in the `conf.py` file for your Sphinx Documentation, where you want to add the links:

```
extensions = [
'sphinx.ext.intersphinx'
]

intersphinx_mapping = {'scancode-toolkit': ('https://scancode-toolkit.readthedocs.io/
↪en/latest/', None)}
```

To show all Intersphinx links and their targets of an Intersphinx mapping file, run:

```
python -msphinx.ext.intersphinx https://scancode-toolkit.readthedocs.io/en/latest/
↪objects.inv
```

Warning: `python -msphinx.ext.intersphinx https://scancode-toolkit.readthedocs.io/objects.inv` will give error.

This enables you to create links to the `scancode-toolkit` Documentation in your own Documentation, where you modified the configuration file. Links can be added like this:

```
For more details refer :ref:`scancode-toolkit:doc_style_guide`.
```

You can also not use the `scancode-toolkit` label assigned to all links from scancode-toolkit.readthedocs.io, if you don't have a label having the same name in your Sphinx Documentation. Example:

```
For more details refer :ref:`doc_style_guide`.
```

If you have a label in your documentation which is also present in the documentation linked by Intersphinx, and you link to that label, it will create a link to the local label.

For more information, refer this tutorial named Using Intersphinx.

1.2.8 Extra Style Checks

1. Headings

   (Refer) Normally, there are no heading levels assigned to certain characters as the structure is determined from the succession of headings. However, this convention is used in Python's Style Guide for documenting which you may follow:

   # with overline, for parts

   - with overline, for chapters

=, for sections

-, for subsections

^, for sub-subsections

“, for paragraphs

2. Heading Underlines

   Do not use underlines that are longer/shorter than the title headline itself. As in:

```
Correct :

Extra Style Checks
------------------

Incorrect :

Extra Style Checks
------------------------
```

Note: Underlines shorter than the Title text generates Errors on sphinx-build.

3. Internal Links

   Using `:ref:` is advised over standard reStructuredText links to sections (like `` `Section title`_ ``) because it works across files, when section headings are changed, will raise warnings if incorrect, and works for all builders that support cross-references. However, external links are created by using the standard `` `Section title`_ `` method.

4. Eliminate Redundancy

   If a section/file has to be repeated somewhere else, do not write the exact same section/file twice. Use `.. include:: ../README.rst` instead. Here, `../` refers to the documentation root, so file location can be used accordingly. This enables us to link documents from other upstream folders.

5. Using `:ref:` only when necessary

   Use `:ref:` to create internal links only when needed, i.e. it is referenced somewhere. Do not create references for all the sections and then only reference some of them, because this created unnecessary references. This also generates ERROR in `restructuredtext-lint`.

6. Spelling

   You should check for spelling errors before you push changes. Aspell is a GNU project Command Line tool you can use for this purpose. Download and install Aspell, then execute `aspell check <file-name>` for all the files changed. Be careful about not changing commands or other stuff as Aspell gives prompts for a lot of them. Also delete the temporary `.bak` files generated. Refer the manual for more information on how to use.

7. Notes and Warning Snippets

   Every `Note` and `Warning` sections are to be kept in `rst_snippets/note_snippets/` and `rst_snippets/warning_snippets/` and then included to eliminate redundancy, as these are frequently used in multiple files.

1.2.9 Converting from Markdown

If you want to convert a `.md` file to a `.rst` file, this tool does it pretty well. You'd still have to clean up and check for errors as this contains a lot of bugs. But this is definitely better than converting everything by yourself.

This will be helpful in converting GitHub wiki's (Markdown Files) to reStructuredtext files for Sphinx/ReadTheDocs hosting.

1.3 AboutCode Project Overview

AboutCode is a suite of open source projects.

1.3.1 AboutCode Projects

- ScanCode Toolkit: This is a set of code scanning tools to detect the origin and license of code and dependencies. ScanCode Toolkit uses a plug-in architecture to run a series of scan-related tools in one process flow. This is the most popular project and is used by hundreds of software teams. https://github.com/nexB/scancode-toolkit . The lead maintainer is @pombredanne
- Scancode Workbench (formerly AboutCode Manager) This is a desktop application (based on Electron) to review the results of a scan and document your conclusions about the origin and license of software components and packages. https://github.com/nexB/aboutcode-manager . The lead maintainer is @majurg
- DeltaCode is a command line tool to compare scans and determine if and where there are material differences that affect licensing. The lead maintainer is @majurg
- AboutCode Toolkit: This is a set of command line tools to document the provenance of your code and generate attribution notices. AboutCode Toolkit uses small yaml files to document code provenance inside a codebase. https://github.com/nexB/aboutcode-toolkit . The lead maintainer is @chinyeungli
- TraceCode Toolkit: This is a set of tools to trace files from your deployment or distribution packages back to their origin in a development codebase or repository. The primary tool uses strace https://github.com/strace/strace/ to trace system calls on Linux and construct a build graph from syscalls to show which files are used to build a binary. We are contributors to strace. Maintained by @pombredanne
- VulnerableCode: an emerging server-side application to collect and track known package vulnerabilities.
- Conan: "conan" stands for "CONtainer ANalysis" and is a tool to analyze the structure and provenance of software components in Docker images using static analysis. https://github.com/nexB/conan Maintained by @pombredanne
- license-expression: This is a library to parse, analyze, compare and normalize SPDX-like license expressions using a boolean logic expression engine. See https://spdx.org/spdx-specification-21-web-version#h.jxpfx0ykyb60 to understand what a license expression is. See https://github.com/nexB/license-expression for the code. The underlying boolean engine is at https://github.com/bastikr/boolean.py . Both are co-maintained by @pombredanne
- ABCD aka AboutCode Data: is a simple set of conventions to define data structures that all the AboutCode tools can understand and use to exchange data. The specification lives in this repository. .ABOUT files and ScanCode tooklit data are examples of this approach. Other projects such as https://libraries.io and OSS Review Toolkit also use these conventions.

1.4 AboutCode Data : ABCD

1.4.1 Summary

ABCD is an abbreviation for ABout Code Data. The AboutCode Data goal is to provide a simple, standardized and extensible way to document data about software code such that:

- It is a common way to exchange data about code between any nexB tools by import and export.
- It becomes the preferred way to exchange data between nexB tools and other tools.
- It could become a valuable structure to exchange data between any tools concerned with data about software.

ABCD is technology and programming language neutral, preferring JSON or YAML document formats.

ABC Data is structured around a few basic objects: Products, Components, Packages, Files, Parties and Licenses. It is extensible to other specific or future object types.

Objects have "attributes" that are simple name/value pairs. A value can be either a plain value or another object or a list of objects and attributes.

ABC Data is minimally specified by design: only a few basic objects and attributes are documented with conventions to name and structure data and how to define relationships between objects. There is only a small reference dictionary for some well known attributes documented here.

The planned benefit for tools using ABC Data is simplified data exchange and integration between multiple best-of-breed tools.

1.4.2 Context

There is currently no easy way to describe information about code and software in a simple and standardized way. There have been many efforts to provide this data in a more structured way such as:

- SPDX (focused on packages and licenses),
- DOAP (focused on projects),
- The original ABOUT metafile format, and
- The many different software package metadata formats (Maven, NPM, RPM, Deb, etc).

These data structures are fragmented and generally too purpose- or technology-specific.

Recently there have been efforts to collect and expose more data such as:

- libraries.io (a catalog of packages, AGPL-licensed) and dependencyci.com its companion commercial service,
- versioneye.com (a catalog of package versions updates, now MIT-licensed),
- softwarearchive.org (an effort to build an all-encompassing software source code archive),
- sources.debian.net (a Debian-focused code and metadata search facility),
- searchcode.com (an add-supported source code search engine exposing some metadata)
- appstream (a cross-distro effort to normalize desktop package metadata access to Linux desktops https://www.freedesktop.org/software/appstream/docs/).

These efforts are all useful, but they do not address how you can consistently exchange data about code in a user-centric and technology-neutral, normalized way.

Why does this matter? Software and code are everywhere. FLOSS code is exploding with millions of components and packages. The data about this code is out there somewhere but getting it is often too difficult. This is a problem of data normalization, aggregation and exchange.

Whether you consume or produce software, accessing and creating normalized data about your code and the code you use should be made easier such that:

- You can efficiently make code selection and re-use decisions,
- You can discover what is in your code, and
- You can continuously track updates, bugs, licenses, liveliness, quality and security attributes of the code you use or consider using.

With the notable exceptions of SPDX and the earlier versions of the ABOUT format, available data formats about software have been designed first for a specific technology (e.g. Linux distros) or programming language (e.g. maven, npm, etc.) and documentation of code provenance and related attributes has been secondary and minimal. In most cases, the primary focus has been to provide first comprehensive support for package installation, dependency resolution or package building and provenance and licensing information is often treated with lesser details.

1.4.3 ABCD: the AboutCode Data structure

ABCD is an abbreviation for ABout Code Data. The goal is to provide a simple, standardized and extensible way to document things about software code.

In contrast with other approaches, the AboutCode Data structure is focused on providing data that is useful to users first and is not limited to software package data only. AboutCode Data need not be as strictly specified as traditional package manager data formats because its purpose is not to drive a software build, package creation or software installation nor is it to compute the resolution of dependencies. It only provides information (metadata) about the code.

The vision for the ABC Data structure is to provide a common way to exchange data about code between all nexB tools, such that these tools can all import and export data about code seamlessly (TraceCode, ScanCode, AboutCode Manager, AttributeCode, upcoming MineCode, etc.). The ABCD structure should also be the preferred way to exchange data about code between nexB tools and other tools. We may create small adapters to convert other data formats in and out of the ABCD structure and encourage other tool authors to natively support ABC Data, though the main focus is on our tools.

The ABCD structure is technology and programming language neutral and designed so that the parties exchanging data about code can do so reliably with some minimal conventions; and that the data is easily processed by machines and not hard to read by humans.

ABC Data is structured around “objects”. Objects have “attributes” that are simple name/value pairs. A value can be either a plain value or another object or a list of nested objects and attributes.

ABC Data is organized around:

- a few known object types,
- simple conventions to create lists of objects and describe object relationships,
- simple conventions to create attributes as name/value pairs, and
- a small dictionary or vocabulary of well-known attribute names that have a common definition across all tools.

ABC Data is “under-specified” by design: only a few essential objects and attributes are documented here with the conventions on how to structure the ABC Data.

1.4.4 Basic objects describing data about code

At the top level we have these main object types:

- Product(s): a software product, application or system such as a Cost Accounting application.
- Component(s): a software component, such as the PostgreSQL 9 database system, usually a significant or major version
- Package(s): a set of files that comprise a Component as used, such as a postgresql-9.4.5-linux-x86.zip archive. The version is exact and specific.
- File(s): any file and directory identified by a path, such as a binary package or a source code directory or file.

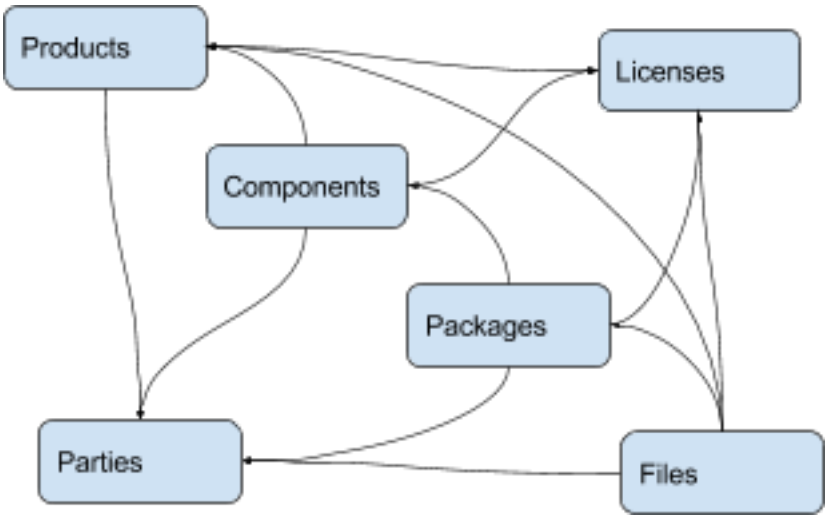
And these secondary, important but less prominent object types:

- Party(ies): a person or an organization. An organization can be a project, formally or informally organized, a company, a department within a company, etc. A Party typically has contact information (such as an email or physical address or home url). A Party may have defaults that apply to much of its software (for an org that creates software) such as a default Apache license for Apache Foundation projects. Parties often relate to other objects through a role relationship such as owner, author, maintainer, etc.
- License(s): information about the license of code. A License typically has a name, text and additional categories. (tags or attributes).

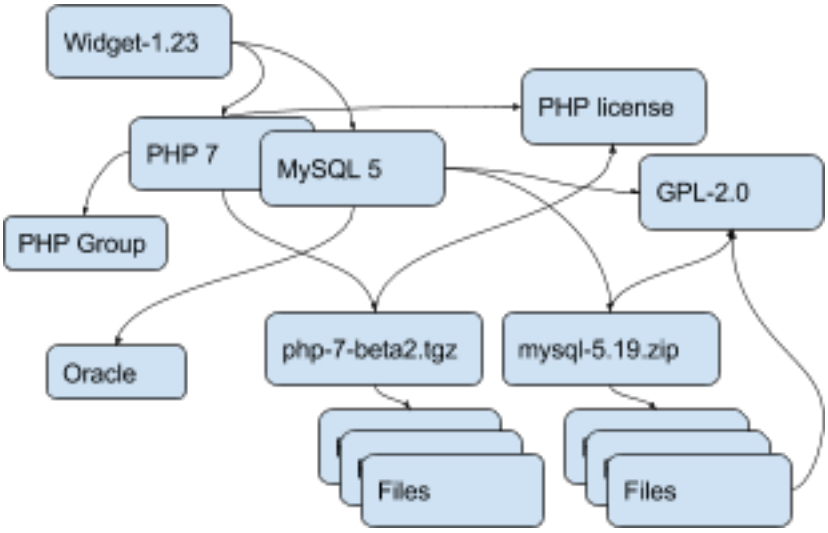
Each of these objects has a few identifying attributes and eventually many tool- or application-specific data attributes. Each tool defines and documents the attributes they can handle and care for. When some agreement is reached on the definition of new attributes or objects, the ABCD dictionary may be updated accordingly with new objects types such as for software security, quality or other interesting aspects.

Objects are interrelated with other objects. Objects can relate to each other via a reference using identifiers pointing to other objects or via an embedded list of objects. The nature of the relationship between two objects can also be specified with additional attributes as needed.

Here are typical relationships between objects:



Here is an example of relationships for a simple Widget product:



Tools can define any custom objects and some used more commonly may be promoted to be documented here over time.

1.4.5 Attribute Names and Values

By convention, a tool receiving ABC Data should process only the data it knows and should ignore unknown attributes or objects. This is important to allow the data structure to evolve and provide some forward and backward compatibility. When an ABCD payload contains data elements that a receiver does not know about, the receiver should still be able to process the known objects and attributes.

- Attributes are name/value pairs.
- Attribute names are always strings, not numbers, not booleans, not any other data format. In these strings, leading and trailing white spaces (spaces, tabs, line returns, etc) are not significant and can be safely ignored or removed.
- Attribute values are one of the standard JSON types: string, number, boolean or null. In strings, leading and trailing white spaces (spaces, tabs, line returns, etc) are not significant and can be safely ignored or removed.
- Self-explicit names should be used rather than obscure names or abbreviations: names should be self-explicit and self-evident.

Except for the data organization conventions described here and the use of the well-known object and attribute names, nothing is mandatory in the ABCD format. This means that even partial, incomplete or sketchy data about code can be transferred in this format.

The meaning of well known object names such as Product, Component, Package, File, Party and License is defined in this document.

1.4.6 Name conventions

- Names are strings composed ONLY of ASCII letters, numbers or underscores. Names cannot start with a number. Names cannot contain spaces nor other punctuation, not even a dot or period.
- Names are NOT case sensitive: upper or lowercase does not matter and the standard is to use lowercase. It is a mistake to use upper or mixed case but this is something a parser receiving ABC Data should recover from nicely by converting the names to lowercase.

- Names are made of English words: there is no provision currently for non-English names. Tools that deal with multilingual content may define their own conventions to provide content in other languages. ABCD may add one of these conventions in the future.
- Parser implementation can be smarter and gentler: For names, anything that is not ASCII or number or underscore can be accepted by a parser and could be replaced by an underscore, including a starting digit if any. Or a parser may provide a warning if there is an unknown name that is very close to a well known name. Or a parser may accept CamelCase and transform names to underscore_case and perform another transformation to conventional ABC Data.
- Names are singular or plural: When a name refers to more than one item, the name of the field is plural and the value is a list of values. For instance "url" and "urls".
- Top level known objects are ALWAYS plural and stored in lists: "parties" or "files" or "products" or "components". This makes it easier to write tools because the top level types are always lists, even when there is a single object in that list.
- A value must not be used as a name: in an attribute name/value pair, the name is always a name, not a value and every value must have a name.
- For instance, this JSON snippet would not be correct where a URL is used as a name:

```
{"http://someurl.com": "this is the home URL"}
```

- Use rather this form to specify a name for the URL attribute:

```
{"url": "http://someurl.com", "note": "this is the home URL"}
```

- But this would be correct when using a list of plain values where "urls" is plural:

```
{"urls": ["http://someurl.com", "http://someurl2.com"]}
```

- An attribute names without a value is not needed. Only names with values are needed, and attributes without values can be omitted: each tool may do what it wants for these cases. For instance it may be handy to provide all attributes even if not defined in an API payload. But when serializing data as YAML, meant for human editing, including all empty values may not help with reading and processing the YAML text. An undefined attribute without a set value should be assigned with the null JSON value: this has the same meaning as if the attribute was not specified and absent from the payload. If you want to specify that an attribute has an empty value and does not have a value (as opposed to have an unknown value) use an empty string instead.
- Avoid abbreviated names, with some exceptions. Names should always be fully spelled out except for:
  - url: uniform resource locator
  - uri: uniform resource identifier
  - urn: uniform resource name
  - vcs: version control system
  - uuid: universally unique identifier, used for uuid4 string https://tools.ietf.org/html/rfc4122.html
  - id: identifier
  - info: information
  - os: operating system
  - arch: architecture
- For some common names we use the common compound form such as:
  - codebase: and not code_base

  - filename: and not file_name
  - homepage: and not home_page

Well known attribute names include:

- name: the name of a product, component, license or package.
- version: the version of a product, component, package.
- description: description text.
- type: some type information about an object. For instance, a File type could be: directory, file or link.
- keywords: a list of keywords about an object. For example, the keywords of a component used to "tag" a component.
- path: the value is the path to a file or directory, either absolute or relative and using the POSIX convention (a forward slash as separator). For Windows paths, replace backslash with forward slashes. Directories should end with a slash in a canonical form.
- key: the value is some key string, slug-like, case-insensitive and composed only of ASCII letters and digits, dash, dot and underscore. No white spaces. For example: org.apache.maven-parent
- role: the value describes the role of a Party in a relationship with other objects. For instance a Party may be the "owner" or "author" of a Component or Package.
- uuid: a uuid4 string https://tools.ietf.org/html/rfc4122.html
- algorithms for checksums: to store checksums we use a name/value pairs where the name is an algorithm such as sha1 and the value is a checksum in hexadecimal such as "sha1": "asasa231212" . The value is the standard/default string created by command line tools such as sha1sum. Supported algorithms may evolve over time. Common checksums include md5, sha1, sha256, sha512.
- notes: some text notes. This is an exception to the singular/plural rule for names: notes is a single text field and not a list.

As the usage of the ABCD structure matures, more well known names will be documented in a vocabulary.

1.4.7 Value conventions

- Attribute values are one of the standard JSON types: string, number, boolean or null. In strings, leading and trailing white spaces (spaces, tabs, line returns, etc) are not significant and can be safely ignored or removed.
- To represent a date/time use the ISO format such as 2016-08-15 defaulting to UTC time zone if the time zone is not specified in the date/time stamp.
- All string values are UTF-8 encoded.

Well known name prefixes or suffixes can be used to provide a type hint for the value type or meaning:

- xxx_count, xxx_number, xxx_level: the value is an integer number. Example: results_count or curation_level
- date_xxx or xxx_date: the value is a date/time stamp in ISO format such as 2016-08-16 (See https://www.ietf.org/rfc/rfc3339.txt). Examples: last_modified_date, date_created
- xxx_url: the value is a URL for web http(s) or ftp url that points to an existing valid web resource (that could possibly no longer exist on the web). Example: homepage_url or api_url
- xxx_uri: the value is a URI typically used as an identifier that may not point to an existing web resource. Example: git://github.com/nexb/scancode-toolkit
- xxx_file or xxx_path: the value is a file path. This can come handy for external files such as a license file. Example: notice_file

- xxx_filename: the value is a file name. Example: notice_filename
- xxx_text: the value is a long text. This is only a hint that it may be large and may span multiple lines. Example: notice_text
- xxx_line: such as start_line and end_line: the value is a line number. The first line number is 1.
- xxx_status: such as configuration_status. Indicates that the value is about some status.
- xxx_name: such as short_name. Indicates that the value is a name. Commonly used for long_name, short_name. The bare name shout be preferred for the obvious and most common way an object is named.
- xxx_flag, is_xxx, has_xxx: such as is_license_notice. Indicates that the string value is a boolean.

1.4.8 Object identifiers

We like objects to be identifiable. There is a natural way to identify and name most objects: for instance, the full name of a person or organization or the name and version of a Component or Package or the path to a File, are all natural identifiers to an object.

However, natural names are not always enough to fully identify an object and may need extra context to reference an object unambiguously. There could be several persons or organizations with the same name at a different address. Or the foo-1.4 Package could be available as a public RubyGem and also as an NPM; or a private Python package foo-1.4 has been created by a company and is also available on Pypi. Or the "foo" Package is the name of a Linux Package, an NPM and a Ruby Package but these three packages are for unrelated components.

Hence each object may need several attributes to be fully identifiable.

For example, public package managers ensure that a name is unique within the confines of a source. "logging" is the unique name of a single Sourceforge project at https://sourceforge.net/projects/logging/. "logging" is the unique name of an Apache project at the Apache Foundation http://logging.apache.org/.

Yet, these two names point to completely different software. In most cases, providing information about the "source" where an identifier is guaranteed to be unique is enough to ensure proper identification. This "source" is easily identified by its internet source name, and an internet source name is guaranteed to be unique globally. The "source" of identifiers is not mandatory but it is strongly encouraged to use as an attribute to provide good unique identifiers. Still, tools exchanging ABC Data must be able to exchange under-specified and partially identified data and may sometimes rely on comparing many attributes of two objects to decide if they are the same.

The minimal way to identify top level objects is the combination of a "source" and a unique identifier within this source. The source can be implicit when two parties are exchanging data privately or explicit using the "source" attribute.

Within a source, we use the most obvious and natural identifies for an object. For example:

- For Products, Components and Packages we can use their name and version.
- For Files we use a path of a file or directory, possibly relative to a package or a product codebase; or a checksum of a file or archive such as a sha1.
- For Parties, we use a name possibly supplemented with a URL or email.
- For all object types we can use a "universally unique id" or UUID-4 (https://tools.ietf.org/html/rfc4122.html)
- For all object types, we can use a key, which is a slug-like string identifier such as a license key.
- For all object types, we can use a URN (https://en.wikipedia.org/wiki/Uniform_resource_name) Tools may also define their own URNs, namespaces and names such as a DejaCode urn is, urn:dje:component:16fusb:1.0

Beyond direct identification, an object may have several alternative identifiers, aka "external references". For instance a Package may have different names and slightly different versions in the Linux, Debian or Fedora distros and a Pypi

Package with yet another name where all these Packages are for the same Component and the same code. Or a Party such as the Eclipse Foundation may be named differently in DejaCode and the NVD CPEs.

To support these cases, the "external_reference(s)" attribute can be used where needed in any object to reference one or more external identifiers and what is the source for this identifier (note: "external" is really a matter of point of view of who owns or produces the ABC Data). An attribute with name suffix of "xxx_reference" may also be used to provide a simpler external reference, such as "approval_reference".

For example, this ABC Data could describe the external id of Party to a CPE and to TechnoPedia (here in a YAML format):

```
parties:
  - name: Apache Foundation
    homepage_url: http://apache.org
    type: organization
    external_references:
        - source: nvd.nist.gov
          identifier: apache
        - source: technopedia.com
          identifier: Apache Foundation (The)
        - source: googlecode.com
          identifier: apache-foundation
```

Other identifiers may also be used, as needed by some tools, such as in hyperlinked APIs.

1.4.9 Organizing data and relationships

Describing relationships between objects is essential in AboutCode Data. There are two ways to describe these relationships: by referencing or by embedding objects.

When using a reference, you relate objects by providing identifiers to these objects and may provide additional object details in separate lists. When embedding, you include not only the reference but also the related object details in another object data. This could include all data about an object or a subset as needed.

For example, this components list embeds a list of two packages.

Note: "components" is always a list, *even when it has a single component*:

```
{"components": [{
    "source": "http://apache.org",
    "name": "Apache httpd",
    "version": "2.3",
    "packages": [
        {"name": "httpd",
         "version": "2.3.4",
         "download_url": "http://apache.org/dist/httpd/httpd-2.3.4.zip",
         "sha1": "acbf23256361abcdf",
         "size": 3267,
         "filename": "httpd-2.3.4.zip"
        },

        {"name": "httpd",
         "version": "2.3.5",
         "download_url": "http://apache.org/dist/httpd/httpd-2.3.5.tar.gz",
         "sha1": "ac8823256361adfcdf",
         "size": 33267,
         "filename": "httpd-2.3.5.tar.gz"
        }
```

(continues on next page)

(continued from previous page)

```
    ]
}]}
```

In this example, the component list references two packages that are listed separately and uses the checksum as package identifiers for the reference. This data is strictly equivalent to the previous example but using a different layout. When all the data is provided, the effect of embedding or referencing objects results in the same data, just organized differently:

```
{"components": [{
    "source": "http://apache.org",
    "name": "Apache httpd",
    "version": "2.3",
    "packages": [
        {"sha1": "aacbf23256361abcdf"},
        {"sha1": "ac8823256361adfcdf"}
    ]
}],

"packages": [
    {"name": "httpd", "version": "2.3.4",
     "download_url":
     "http://apache.org/dist/httpd/httpd-2.3.4.zip",
     "sha1": "acbf23256361abcdf", "size": 23267, "filename": "httpd-2.3.4.zip"},

    {"name": "httpd", "version": "2.3.5",
     "download_url": "http://apache.org/dist/httpd/httpd-2.3.5.tar.gz",
     "sha1": "ac8823256361adfcdf", "size": 33267, "filename": "httpd-2.3.5.tar.gz"}
]}
```

In this third example the packages are referencing one component instead. That component is always wrapped in a components list. The component detail data is not provided. The details may be available elsewhere in a tool that tracks components:

```
"packages": [
    {"name": "httpd", "version": "2.3.4",
     "download_url": "http://apache.org/dist/httpd/httpd-2.3.4.zip",
     "sha1": "acbf23256361abcdf", "size": 23267, "filename": "httpd-2.3.4.zip",
     "components": [
        {"source": "http://apache.org", "name": "Apache httpd", "version": "2.3"}
     ]
    },

    {"name": "httpd", "version": "2.3.5",
     "download_url":"http://apache.org/dist/httpd/httpd-2.3.5.tar.gz",
     "sha1": "ac8823256361adfcdf", "size": 33267, "filename": "httpd-2.3.5.tar.gz",
     "components": [
        {"source": "http://apache.org", "name": "Apache httpd", "version": "2.3"}
     ]
    }
]
```

Relationships can be documented with this approach in different ways. Typically when the primary concern is about a Product, then the Product object may embed data about its Components. When the primary concern is Packages, they may embed or reference Products or Components or files. For example:

- A tool may prefer to provide data with products or components as top level objects. The components used in a Product are naturally embedded in the products.

- A tool concerned more with files, will provide files as top level objects and may embed package details when they are found for a file or directory path.
- Another tool may focus on packages and provide packages first with component references and possibly embedded files. A matching tool may provide packages first and reference matched files. The file paths of a package are naturally embedded in the package, though using references may help keep the data simpler when there is a large volume of files.
- A tool that generates attribution documentation may focus first on components and second on licenses or packages references.
- A tool dealing with security vulnerabilities may define a Vulnerability object and reference Packages and Files that are affected by a Vulnerability.

To better understand the embedding or referencing relationships:

- using references is similar to a tabular data layout, akin to a relational database table structure
- using embedding is similar to a tree data layout such as in a file/directory tree or nested data such as XML.

Another way to think about these relationships is a "GROUP BY" statement in SQL. The data can be grouped-by Component, then Packages or grouped-by Files then Components.

Both referencing and embedding layouts can be combined freely and are not mutually exclusive. When using both at the same time, some care is needed to avoid creating documents with conflicting or duplicated data that is referenced and embedded at the same time.

Using references is often useful when there is an agreement on how to reference objects between two tools or parties. For instance, when using nexB tools, a unique and well defined license key is used to reference a license rather than embedding the full license details. A concise reference to the name and version of a public package from a well known package repository such as RPM or Maven can be used to the same effect. Or an SPDX license identifier can be used to reference an SPDX-listed license without having to embed its full license text.

The nature of the relationship between two objects can be specified when it is not obvious and requires some extra specification. Each tool can define additional attributes to document these. For instance a common relationship between a party and a product or component is a role such as owner. For packages a role can be maintainer, author, etc. Or the license of a file or package may be the "asserted" license by the project authors. It may differ from the "detected" license from a scan or code inspection and may further differ from a "concluded" license or a "selected" license when there is a license choice. At the package and license level the types of relationships documented in the SPDX specification are a good source for more details. For example this component references two parties where one is the author and the other is the maintainer documented using a role attribute:

```
"components": [{
    "source": "http://apache.org",
    "name": "Apache httpd",
    "version": "2.3",
    "parties": [
        {"name": "John Doe", "type": "person", "role": "author"},
        {"name": "Jane Smith", "type": "person", "role": "maintainer"},
        {"name": "Jane Smith", "type": "person", "role": "owner"},
    ]
}]
```

1.4.10 Document format conventions

The default ABC Data format is JSON (though it can be serialized to anything else that would preserve its structure). YAML is also supported and preferred for storage of simple documents that document one or a few top level objects and that need to be edited by a human.

The data structure by nested name/value pairs attributes and lists of values maps naturally to the corresponding JSON and YAML constructs. In JSON-speak these are arrays (lists) and objects (name/value pairs).

ABC Data can be provided as simple files or embedded in some API payload. As files, their content can be either JSON or YAML and should have either a .json or .yml extension by convention. For backwards compatibility with previous AboutCode conventions, the .ABOUT extension can be used for YAML documents. For instance this is used in the legacy about_code_tool and its successors. The DocumentCode tool can store individual attribution data in a .ABOUT yml file.

The top level structure of an ABC Data block is always a JSON object or YAML dictionary. Depending on the context this top level structure may be wrapped in another data structure (for instance when exchanging AboutCode Data in some web api, the API may provide ABC Data as a payload in a "results" or "body" or "data" block and also have some "headers" or "meta" block).

The top level elements must contain at least one of the object names and a list of objects such as here with a list of files:

```
files:
    - path: this/foo/bar
      size: 123
      sha1: aaf35463472abcd
    - path: that/baz
```

Optionally an "aboutcode_version" attribute can be added at the top level to document which version of the AboutCode Data structure is used for a document. For example: aboutcode_version: 4.0

Order of attributes matters to help reading documents: tools that write ABC Data should attempt to use a consistent order for objects and attribute names rather than a random ordering. However, some tools may not be able to set a specific order so thi is only a recommendation. The preferred order is to start with identifiers and keys and from the most important to the least important attributes, followed by attributes grouped logically together, followed by related objects.

1.4.11 References between documents and payload, embedding other files

ABC Data may reference other data. For instance in a hyperlinked REST API a list of URLs to further invoke the API and get license' details may be provided with an api_url attribute to identify which API calls to invoke. The ways to reference data and the semantics and mechanics of each of these embeddings or references needed to get the actual data are not specified here. Each tool may offer its own mechanism. A convention for an hyperlinked REST API JSON payload could be to use api_url(s) identifier to specify additional "GET"able endpoints. The AttributeCode tool use *_file attributes in YAML or JSON documents to reference external license and notices text files to load with the text content.

Another convention is used in ScanCode to reference license texts and license detection rules by key: An ABC Data YAML file contains the ABC Data. And side by side there is a file with the same base name and a LICENSE, SPDX or NOTICE, RULE, extension that contains the actual text corresponding to the license, the SPDX text or the rule text. The convention here is to use an implicit reference between files because they have the same base name and different extensions.

In the future, we may specify how to embed an external ABC Data file in another ABC Data file; this would only apply to file-based ABC Data payload though and could not apply to hyperlinked REST APIs.

1.4.12 Document-as-files naming, exchange and storage

Each tool handling ABC Data may name an ABC Data file in any manner and store the data in any way that is appropriate. The structure is a set of data exchange conventions and may be used for storage but nothing is specified on how to do this.

For consistency, tools consuming AboutCode Data are encouraged to use the same data structure internally and in their user interface to organize and name the data, but this is only a recommendation.

For instance, the AttributeCode tool uses a convention to store ABC Data as YAML in a file with a .ABOUT extension and uses the ABC Data structures internally and externally.

When exchanging data (for instance over an API), the API provider of ABC Data should support a request to return either embedded data or data by reference and ideally allow the caller to specify which objects and attributes it is interested in (possibly in the future using something like GraphQL).

When interacting with tools through an API, the conversation could start by sending an ABC Data payload with some extra request data and receiving an ABC Data payload in return. For instance, when requesting matching packages from a matching tool, you could start by passing scan data with checksums for several files at once and receive detailed data for each of the matched files or packages.

1.4.13 Documenting and validating attributes

Each tool handling ABC Data may only be interested in processing certain objects and attributes when accepting data in, or when providing data out. Attributes that are unknown should be ignored. To document which objects and which attributes a tool can handle, a tool should provide some documentation. The documentation format is not specified here, but it could use a JSON schema in the future. This should include documentation regarding if and how data is validated, and when and how errors or warnings are triggered and provided when there is a validation error. For example, a validation could be to check that an SPDX license id exists at SPDX or that a URL is valid.

1.4.14 Notes on YAML format

YAML is the preferred file format for ABC Data destined for reading or writing primarily by humans.

- Block-style is better.
- When you write AboutCode Data as YAML, you should privilege block-style and avoid flow-style YAML which is less readable for humans.
- Avoid Multi-document YAML.
- Multi-document YAML documents should be avoided (when using the — separators).
- Beware of parser shenanigans: Most YAML parsers recognize and convert automatically certain data types such as numbers, booleans or dates. You should be aware of this because the ABC Data strings may contain date stamps. You may want to configure a YAML parser to deactivate some of these automated format conversions to avoid unwanted conversions.

1.4.15 Notes on JSON Format

JSON is the preferred file format for ABC Data destined for reading and writing primarily by machines.

- "Streamable" JSON with JSON-lines.

A large JSON document may benefit from being readable line-by-line rather than loaded all at once in memory. For this purpose, the convention is to use JSON lines where each line in the document is a valid JSON document itself: this enables reading the document in line-by-line increments. The preferred way to do so is to provide one ABCD top level object per document where the first line contains meta information about the stream such as a notice, a tool version or the aboutcode version.

- Avoid escaped slash.

The JSON specification says you CAN escape forward slash, but this is optional. It is best to avoid escaping slash when not needed for better readability.

For instance for URLs this form:

```
"https://enterprise.dejacode.com/component_catalog/nexB/16fusb/1.0/"
```

should be preferred over this escaped form when backslashes are not needed:

```
"https:\\/\\/enterprise.dejacode.com\\/component_catalog\\/nexB\\/16fusb\\/1.0\\/"
```

1.4.16 Notes on embedding ABC Data in source code files.

It could be useful to include ABC Data directly in a source code file, such as to provide structured license and provenance data for a single file. This requires of course a file modification. While this is not a preferred use case, it can be handy to document your own code one file at a time. Using an external ABC Data file should be preferred but here are conventions for this use case:

- The ABC Data should be embedded in a top level block of comments.
- Inside that block of comments the preferred format is YAML.
- How a tool collects that ABC Data when embedded in code is to be determined.
- Tools offering such support should document and eventually enforce their own conventions.

1.4.17 Notes on spreadsheet and CSV files

ABC Data does not support or endorse using CSV or spreadsheets for data exchange.

CSV and other spreadsheet file formats are NOT recommended to store ABC Data. In most cases you cannot store a correct data set in a spreadsheet. However, these tools are also widely used and convenient. Here are some recommendations when you need to communicate ABC data in a CSV or spreadsheet format: even though ABC Data is naturally nested and tree-like, it should be possible to serialize certain ABCD objects as flat, tabular data.

- Naming columns

The table column names may need to be adjusted to correctly reference the multiple level of object and attribute nesting using a dot as a separator. The dot or period is otherwise not allowed in attribute names. For example, you could use files.path for files or components.name to reference a component name. Some tools may prefer to create tabular files with their own column names and layout, and provide mappings to ABC Data attribute and object names.

- Example for an inventory:

Since ABC Data can be related by reference, the preferred (and cumbersome) way to store ABC Data in a spreadsheet is to use one tab for each object type and use identifying attributes to relate objects between each others across tabs. For instance, in a Bill of Materials (BOM) spreadsheet for a Product, you could use a tab to describe the Product attributes and another tab to describe the Components used in this Product and possibly additional tabs to describe the related packages and files corresponding to these

- Care is needed for Packages, Components and other names and for dates, versions, unicode and UTF-8 to avoid damaging content (aka. mojibake)

Spreadsheet tools such as Excel or LibreOffice automatically recognize and convert data to their own format: a date of 20016-08-17 may be converted to a date number when a CSV is loaded and difficult to recover as a correct original date stamp string afterwards. Or a version 1.0 may be irreversibly converted to 1 or 1.90 to 1.9 losing important version information.

Spreadsheet tools may not recognize and handle properly UTF-8 texts and damage descriptions and texts. These tools may also treat strings starting with the equal sign as a formula. When incorrectly recognizing special accentuated characters this may damage texts creating what is called "mojibake" (See https://en.wikipedia.org/wiki/Mojibake)

Always use these tools with caution and be prepared for damage to your data if you use these tools to save or create ABC Data.

Impact on AttributeCode

As an integration tool, AttributeCode itself may specify only a very few elements.

The new structure will need to be implemented. Here could be an example in YAML:

```
aboutcode_version: 4.0
components:
 -  source: dejacode.com
    name: bitarray
    version: 0.8.1
    homepage_url: https://github.com/ilanschnell/bitarray
    copyright: Copyright (c) Ilan Schnell and others
    files:
        - path: some/directory/
          type: dir
        - path: bitarray-0.8.1-cp27-cp27m-macosx_10_9_intel.whl
        - path: someotherdir/bitarray-0.8.1-cp27-cp27m-manylinux1_i686.whl
        - path: bitarray-0.8.1-cp27-cp27m-manylinux1_x86_64.whl
        - path: bitarray-0.8.1-cp27-cp27m-win_amd64.whl
        - path: bitarray-0.8.1-cp27-cp27m-win32.whl
        - path: bitarray-0.8.1-cp27-cp27mu-manylinux1_i686.whl
        - path: bitarray-0.8.1-cp27-cp27mu-manylinux1_x86_64.whl
        - path: bitarray-0.8.1-cp27-none-macosx_10_6_intel.whl
        - path: bitarray-0.8.1.tar.gz

    parties:
      - role: owner
        name: Ilan Schnell

    packages:
      - download_url: http://pypi.python.org/packages/source/b/bitarray/bitarray-0.8.
↪1.tar.gz
        sha1: 468456384529abcdef342

    license_expression: psf

    licenses:
      - source: scancode.com
        key: psf
        text_file: PSF.LICENSE
```

And here would be similar data in JSON:

```
{"components": [{
                "name": "bitarray",
                "version": "0.8.1"
                "homepage_url": "https://github.com/ilanschnell/bitarray",
                "copyright": "Copyright (c) Ilan Schnell and others",
                "license_expression": "psf",
```

(continues on next page)

(continued from previous page)

```
                "licenses": [{"key": "psf", "text_file": "PSF.LICENSE", "source":
↪"scancode.com"}],
                "packages": [{"download_url": "http://pypi.python.org/packages/source/
↪b/bitarray/bitarray-0.8.1.tar.gz"
                              "sha1": "468456384529abcdef342"
                 }],
                "parties": [{"name": "Ilan Schnell", "role": "owner"}],

                "files": [{"path": "some/directory/", "type": "dir"},
                          {"path": "bitarray-0.8.1-cp27-cp27m-macosx_10_9_intel.whl"},
                          {"path": "bitarray-0.8.1-cp27-cp27m-manylinux1_i686.whl"},
                          {"path": "bitarray-0.8.1-cp27-cp27m-manylinux1_x86_64.whl"},
                          {"path": "bitarray-0.8.1-cp27-cp27m-win_amd64.whl"},
                          {"path": "bitarray-0.8.1-cp27-cp27m-win32.whl"},
                          {"path": "bitarray-0.8.1-cp27-cp27mu-manylinux1_i686.whl"},
                          {"path": "bitarray-0.8.1-cp27-cp27mu-manylinux1_x86_64.whl"},
                          {"path": "bitarray-0.8.1-cp27-none-macosx_10_6_intel.whl"},
                          {"path": "bitarray-0.8.1.tar.gz"}],
                }],

 aboutcode_version: "4.0"}
```

Impact on ScanCode Toolkit

The new format will need to be implemented for scan results in general and for packages in particular.

ScanCode will specify Package and several attributes related to scanning and referencing clues for files, directories and packages.

Alternatively Packages could be extracted to an independent PackagedCode library.

The changes will minimize impact on the layout of the scan results. Here is an example of a scan payload in ABCD format: this is essentially the standard scan format:

```
{
  "scancode_notice": "Generated with ScanCode and provided .......",
  "scancode_version": "2.0.0.dev0",
  "files_count": 7,
  "files": [
    {
      "path": "samples/JGroups/src/",
      "type": "directory",
      "files_count": 29
      "licenses" : [
          { "key":"apache-2.0",
            "concluded": true}
      ]
    }
    {
      "path": "samples/JGroups/src/GuardedBy.java",
      "date": "2015-12-10",
      "programming_language": "Java",
      "sha1": "981d67087e65e9a44957c026d4b10817cf77d966",
      "name": "GuardedBy.java",
      "extension": ".java",
      "file_type": "ASCII text",
```

(continues on next page)

(continued from previous page)

```
      "is_text": true,
      "is_source": true,
      "md5": "c5064400f759d3e81771005051d17dc1",
      "type": "file",
      "is_archive": null,
      "mime_type": "text/plain",
      "size": 813,
      "copyrights": [

AboutCode Manager

As a primary GUI for data review and integration, AboutCode Manager will need to be fluent in ABC Data to read/write ABC Data locally and remotely through API from several sources.

The short term changes would include:

- Support reading ABC Data from ScanCode
- Writing ABC Data, adding conclusions as related objects in the proper lists

New and Future tools

- TraceCode: would likely specify low level attributes for files (such as debug symbols, etc) and how files are related from devel to deploy and back.
- VulnerableCode: would likely specify a new Vulnerability object and the related attributes and may track several identifiers to the NIST NVD CPE and CVE.
- DeltaCode: would likely specify attributes to describe the changes between codebases, files, packages.

COMMUNITY DOCS

2.1 GSoC – Google Summer of Code

Google Summer of Code is a global annual program focused on introducing students to open source software development. GSoC is completely online designed to encourage university student participation in open source software development. It was started by Google in 2005. More about GSoc - <https://summerofcode.withgoogle.com/about/>_

2.1.1 Google Summer of Code 2019 - Final report

Project: Approximately similar file detection in DeltaCode

Arnav Mandal <arnav.mandal1234@gmail.com>

Project Overview

DeltaCode is a tool to compare and report scan differences. It takes JSON files as an input which is the output of ScanCode-toolkit as well. When comparing files, it only uses the exact comparison. By exact comparison, I mean it compares the hash value of the files. The output of DeltaCode is a JSON/CSV file which includes the details of the scan such as delta score, delta count, etc. The goal of this project is to improve the usefulness of the delta by also finding files that are mostly the same (e.g. quasi or near duplicates) vs. files that are completely different. After this project, DeltaCode would be able to detect similar files in a directory approximately.

Requirements of the project

- Provided two files using ScanCode-toolkit, the new near-duplicate detection should return the distance between the two files.
- The code should be seamlessly integrated with ScanCode-toolkit. It should be highly configurable by the maintainers.
- The strictness of near-duplicates should be noted and adjusted by a threshold variable.

The Project

- Addition of new fingerprint plugin in the ScanCode Toolkit.
- Implementation and integration of the fingerprint generation algorithm in the ScanCode Toolkit codebase.
- Implementation of distance finding algorithm between the files and process them further in the DeltaCode codebase.

- Integration of fingerprint field in the JSON file to compare the deltas and provide them with appropriate scores.
- Make changes to old unit tests and addition of new unit tests in ScanCode Toolkit as well as DeltaCode.

I have completed all the tasks that were in the scope of this GSoC project.

Pull Requests

- https://github.com/nexB/scancode-toolkit/pull/1576 [Closed] (something went wrong while rebasing)
- https://github.com/nexB/scancode-toolkit/pull/1651 [Merged]
- https://github.com/nexB/deltacode/pull/128 [Merged]

Links

- DeltaCode

I've had a wonderful time during these three months and have learned plenty of things. I would really like to thank @pombredanne, @majurg, and @JonoYang for their constant support throughout the journey. From good job claps to nit-picky constructive code-reviews, I enjoyed every bit of this GSoC project.

2.1.2 Google Summer of Code 2019

AboutCode is participating in the Google Summer of Code in 2019 as a mentoring org. This page contain all the information for students and anyone else interested in helping.

AboutCode is a family of FOSS projects to uncover data ... about software code:

- where does the code come from? which software package?
- what is its license? copyright?
- is the code secure, maintained, well coded?

All these are questions that are important to answer: there are million of free and open source software components available on the web for reuse.

Knowing where a software package comes from, what is its license and if it is vulnerable and what's its licensing should be a problem of the past such that everyone can safely consume more free and open source software.

Join us to make it so!

Our tools are used to help detect and report the origin and license of source code, packages and binaries as well as discover software and package dependencies, and in the future track security vulnerabilities, bugs and other important software package attributes. This is a suite of command line tools, web-based and API servers and desktop applications.

Table of Contents

AboutCode projects are...

- ScanCode Toolkit is a popular command line tool to scan code for licenses, copyrights and packages, used by many organizations and FOSS projects, small and large.
- Scancode Workbench (formerly AboutCode Manager) is a JavaScript, Electron-based desktop application to review scan results and document your origin and license conclusions.
- AboutCode Toolkit is a command line tool to document and inventory known packages and licenses and generate attribution docs, typically using the results of analyzed and reviewed scans.
- TraceCode Toolkit is a command line tool to find which source code file is used to create a compiled binary and trace and graph builds.
- DeltaCode is a command line tool to compare scans and determine if and where there are material differences that affect licensing.
- ConAn : a command line tool to analyze the code in Docker and container images
- VulnerableCode : an emerging server-side application to collect and track known package vulnerabilities.
- license-expression : a library to parse, analyze, simplify and render boolean license expression (such as SPDX)

We also work closely, contribute and co-started several other orgs and projects:

- Package URL which is an emerging standard to reference software packages of all types with simple, readable and concise URLs.
- SPDX aka. Software Package Data Exchange, a spec to document the origin and licensing of packages.
- ClearlyDefined to review and help FOSS projects improve their licensing and documentation clarity.

Contact

Join the chat online or by IRC at https://gitter.im/aboutcode-org/discuss Introduce yourself and start the discussion!

For personal issues, you can contact the primary org admin directly: @pombredanne and pombredanne@gmail.com

Please ask questions the smart way: http://www.catb.org/~esr/faqs/smart-questions.html

Technology

Discovering the origin of code is a vast topic. We primarily use Python for this and some C/C++ (and eventually some Rust and Go) for performance sensitive code and Electron/JavaScript for GUI.

Our domain includes text analysis and processing (for instance for copyrights and licenses detection), parsing (for package manifest formats), binary analysis (to detect the origin and license of binaries, which source code they come from, etc.) as well as web based tools and APIs (to expose the tools and libraries as web services) and low-level data structures for efficient matching (such as Aho- Corasick and other automata).

Skills

Incoming students will need the following skills:

- Intermediate to strong Python programming. For some projects, strong C/C++ and/or Rust is needed too.
- Familiarity with git as a version control system
- Ability to set up your own development environment
- An interest in FOSS licensing and software code and origin analysis

We are happy to help you get up to speed, but the more you are able to demonstrate ability and skills in advance, the more likely we are to choose your application!

About your project application

We expect your application to be in the range of 1000 words. Anything less than that will probably not contain enough information for us to determine whether you are the right person for the job. Your proposal should contain at least the following information, plus anything you think is relevant:

- Your name
- Title of your proposal
- Abstract of your proposal
- Detailed description of your idea including explanation on why is it innovative and what it will contribute to the project
  - hint: explain your data structures and you planned main processing flows in details.
- Description of previous work, existing solutions (links to prototypes, bibliography are more than welcome)
- Mention the details of your academic studies, any previous work, internships
- Relevant skills that will help you to achieve the goal (programming languages, frameworks)?
- Any previous open-source projects (or even previous GSoC) you have contributed to and links.
- Do you plan to have any other commitments during GSoC that may affect your work? Any vacations/holidays? Will you be available full time to work on your project? (Hint: do not bother applying if this is not a serious full time commitment during the GSoC time frame)

Join the chat online or by IRC at https://gitter.im/aboutcode-org/discuss introduce yourself and start the discussion!

The best way to demonstrate your capability would be to submit a small patch ahead of the project selection for an existing issue or a new issue.

We will **always** consider and prefer a project submissions where you have submitted a patch over any other submission without a patch.

You can pick any project idea from the list below. If you have other ideas that are not in this list, contact the team first to make sure it makes sense.

Our Project ideas

Here is a list of candidate project ideas for your consideration. Your own ideas are welcomed too! Please chat about them to increase your chances of success!

ScanCode ideas

Improve Copyright detection accuracy and speed in ScanCode

Copyright detection is reasonably good by the slowest scanner in ScanCode. It is based on NLTK part of speech (PoS) tagging and a copyright grammar. The exact start and end lines where a copyright is found are approximate.

The goal of this project is to refactor Copyright detection for speed and simplicity possibly implementing a new parser (PEG?, etc.) or re-implementing core elements in Rust with a Python binding for speed or using a fork of NLTK or any other tool to be faster and more accurate.

This would include also keeping track of line numbers and offsets where copyrights are found.

Also we detect copyrights that are part of a standard license text (e.g. FSF copyright in a GPL text) and we should be able to filter these out.

  - https://github.com/nexB/scancode-toolkit/issues/295
- **Mentors**
  - @majurg https://github.com/majurg

Improve Programming language detection and classification in ScanCode

ScanCode programming language detection is not as accurate as it could be and this is important to get this right to drive further automation. We also need to automatically classify each file in facets when possible.

The goal of this project is to improve the quality of programming language detection (which is using only Pygments today and could use another tool, e.g. some Bayesian classifier like Github linguist, enry ?). And to create and implement a flexible framework of rules to automate assigning files to facets which could use some machine learning and classifier.

Improve License detection accuracy and speed in ScanCode

ScanCode license detection is using a sophisticated set of techniques base on automatons, inverted indexes and sequence matching. There are some cases where license detection accuracy could be improved (such as when scanning long notices). Other improvements would be welcomed to ensure the proper detected license text is collected in an improved way. Dealing with large files sometimes trigger a timeout and handling these cases would be needed too (by breaking files in chunks). The detection speed could also be improved possibly by porting some critical code sections to C or Rust and that would need extensive profiling.

  - @mjherzog https://github.com/mjherzog
  - @pombredanne https://github.com/pombredanne

Improve ScanCode scan summarization and deduction

The goal of this project is to take existing scan results and infer summaries and perform some deduction of license and origin at a higher level, such as the licensing or origin of a whole directory tree. The ultimate goal is to automate the conclusion of a license and origin based on scans. This could include using statistics and machine learning techniques such as classifiers where relevant and efficient.

This should be implemented as a set of ScanCode plugins and further the summarycode module plugins.

  - @JonoYang https://github.com/JonoYang

Create Linux distros and FreeBSD packages for ScanCode.

The goal of this project is to ensure that we have proper packages for Linux distros and FreeBSD for ScanCode.

The first step is to debundle pre-built binaries that exist in ScanCode such that they come either from system-packages or pre-built Python wheels. This covers libarchive, libmagic and a few other native libraries and has been recently completed.

The next step is to ensure that all the dependencies from ScanCode are also available as distro packages.

The last step is to create proper distro packages for RPM, Debian, FreeBSD and as many other distros such as Nix and GUIX, Alpine, Arch and Gentoo (and possibly also AppImage.org packages and Docker images) and submit these package to the distros.

As a bonus, the same could then be done for AboutCode toolkit and TraceCode.

This requires a good understanding of packaging and Python.

DeltaCode projects

Approximately Similar file detection in DeltaCode

DeltaCode is a tool to compare and report scan differences. When comparing files, it only uses exact comparison. The goal of this project is to improve the usefulness of the delta by also finding files that are mostly the same (e.g. quasi or nrea duplicates) vs. files that are completely different. Then the DeltaCode comparison core should be updated accordingly to detect and report material changes to scans (such as new, update or removed licenses, origins and packages) when changes are also meterial in the code files (e.g. such that small changes may be ignored)

  - @johnmhoran https://github.com/johnmhoran

TraceCode projects

Static analysis of binaries for build tracing in TraceCode

TraceCode does system call tracing only today. The primary goal of this project is to create a tool that provides the same results as the strace-based tracing but would be using using ELF symbols, DWARF debug symbols, signatures or string matching to determine when and how a source code file is built in a binary using only a static analysis. The primary target should be Linux executables, though the code should be designed to be extensible to Windows PE and macOS Dylib and exes.

- **Level**

- **Mentor**
  - @pombredanne https://github.com/pombredanne

Improve dynamic build tracing in TraceCode

TraceCode does system call tracing and relies on kernel-space system calls and in particular tracing file descriptors. This project should improve the tracing of the lifecycle of file descriptors when tracing a build with strace. We need to improve how TraceCode does system call tracing by improving the way we track open/close file descriptors in the trace to reconstruct the lifecycle of a traced file. This requires to understand and dive if the essence of system calls and file lifecycle from a kernel point of view and build datastructure and code to reconstruct user-space file activity from the kernel traces along a timeline.

This project also would cover updating TraceCode to use the Click command line toolkit (like for ScanCode).

Conan and Other projects

Containers and VM images static package analysis

The goal of this project is to further the Conan container static analysis tool to effectively support proper inventory of installed packages without running the containers.

This includes determining which packages are installed in Docker layers for RPMs, Debian or Alpine Linux in a static way. And this may eventually require the integration with ScanCode.

DependentCode: a mostly universal Package dependencies resolver

The goal of this project is to create a tool for a universal package dependencies resolution using a SAT solver that should leverage the detected packages from ScanCode and the Package URLs and could provide a good enough way to resolve package dependencies for many system and application package formats. This is a green field project.

VulnerableCode Package security vulnerability correlated data feed

This project is to futher and evolve the VulnerableCode server and software package vulnerabilities data aggregator.

VulnerableCode was started as a GSoC project in 2017. Its goal is to collect, aggregate and correlate vulnerabilities data and provide semi-automatic correlation. In the end it should provide the basis to report vulnerabilities alerts found in packages identified by ScanCode.

This is not trivial as there are several gaps in the CVE data and how they relate to packages as they are detected by ScanCode or else.

The features and TODO for this updated server would be:

- Aggregate more and new packages vulnerabilities feeds,
- Automating correlation: add smart relationship detection to infer new relatiosnhips between available packages and vulnerabilities from mining the graph of existing relations.
- Create a ScanCode plugin to report vulnerabilities with detected packages using this data.
- Integrate API lookup on the server withe the AboutCode Manager UI
- Create a UI and model for community curation of vulnerability to package mappings, correlations and enhancements.

High volume matching automatons and data structures

Finding similar code is a way to detect the origin of code against an index of open source code.

To enable this, we need to research and create efficient and compact data structures that are specialized for the type of data we lookup. Given the volume to consider (typically multi billion values indexed) there are special considerations to have compact and memory efficient dedicated structures (rather than using a general purpose DB or Key/value pair store) that includes looking at automata, and memory mapping. This types of data structures should be implemented in Rust as a preference (though C/C++ is OK) and include Python bindings.

There are several areas to research and prototype such as:

- A data structure to match efficiently a batch of fix-width checksums (e.g. SHA1) against a large index of such checksums, where each checksum points to one or more files or packages. A possible direction is to use finite state transducers, specialized B-tree indexes, blomm-like filters. Since when a codebase is being matched there can be millions of lookups to do, the batch matching is preferred.
- A data structure to match efficiently a batch of fix-width byte strings (e.g. LSH) against a large index of such LSH within a fixed hamming distance, where each points to one or more files or packages. A possible direction is to use finite state transducers (possibly weighted), specialized B-tree indexes or multiple hash-like on-disk tables.
- A memory-mapped Aho-Corasick automaton to build large batch tree matchers. Available Aho-Corasick automatons may not have a Python binding or may not allow memory-mapping (like pyahocorasick we use in ScanCode). The volume of files we want to handle requires to reuse, extend or create specialized tree/paths matching automatons that can handle eventually billions of nodes and are larger than the available memory. A possible direction is to use finite state transducers (possibly weighted).
- Feature hashing research: we deal with many "features" and hashing to limit the number and size of the each features seems to be a valuable thing. The goal is to research the validaty of feature hashing with short hashes (15, 16 and 32 bits) and evaluate if this leads to acceptable false-positive and loss of accuracy in the context of the data structures mentioned above.

Then using these data structures, the project should create a system for matching code as a Python-based server exposing a simple API. This is a green field project.

Mentoring

We welcome new mentors to help with the program and require some good unerstanding of the project codebase and domain to join as a mentor. Contact the team on Gitter.

2.1.3 Google Summer of Code 2018

See *Contributor Project Ideas (old)*.

2.1.4 Google Summer of Code 2017

Welcome to AboutCode! This year AboutCode is a mentoring Organization for the Google Summer of Code 2017 edition.

AboutCode is a project to uncover data ... about software code:

- where does it come from?
- what is its license? copyright?
- is it secure, maintained, well coded?

All these are questions that are important to find answers to when there are million of free and open source software components available on the web.

Where software comes from and what is its license should be a problem of the past, such that everyone can safely consume more free and open source software. Come and join us to make it so!

Our tools are used to help detect and report the origin and license of source code, packages and binaries, as well as discover software and package dependencies, track vulnerabilities, bugs and other important software component attributes.

Contact

Subscribe to the mailing list at https://lists.sourceforge.net/lists/listinfo/aboutcode-discuss and introduce yourself and start the discussion! The mailing list is usually the better option to avoid timezone gaps.

The list archive have also plenty of interesting information. Someone may have asked your question before. Search and browse the archives at https://sourceforge.net/p/aboutcode/mailman/aboutcode-discuss/ !

For short chats, you can also join the #aboutcode IRC channel on Freenode or the Gitter channel at https://gitter.im/aboutcode-org/discuss

For personal issues, you can contact the org admin directly: @pombredanne and pombredanne@gmail.com

Please ask questions the smart way: http://www.catb.org/~esr/faqs/smart-questions.html

Technology

Discovering the origin of code is a vast topic. We primarily use Python for this and some C/C++ and JavaScript, but we are open to using any other language within reason.

Our domain includes text analysis and processing (for instance for copyrights and licenses), parsing (for package manifest formats), binary analysis (to detect the origin and license of binaries, which source code they come from, etc) as well as web based tools and APIs (to expose the tools and libraries as web services).

About your project application

We expect your application to be in the range of 1000 words. Anything less than that will probably not contain enough information for us to determine whether you are the right person for the job. Your proposal should contain at least the following information, plus anything you think is relevant:

- Your name
- Title of your proposal
- Abstract of your proposal
- Detailed description of your idea including explanation on why is it innovative and what it will contribute
  - hint: explain your data structures and the main processing flows in details.
- Description of previous work, existing solutions (links to prototypes, bibliography are more than welcome)
- Mention the details of your academic studies, any previous work, internships
- Relevant skills that will help you to achieve the goal (programming languages, frameworks)?
- Any previous open-source projects (or even previous GSoC) you have contributed to and links.
- Do you plan to have any other commitments during GSoC that may affect your work? Any vacations/holidays? Will you be available full time to work on your project? (Hint: do not bother applying if this is not a serious full time commitment)

Subscribe to the mailing list at https://lists.sourceforge.net/lists/listinfo/aboutcode-discuss or join the #aboutcode IRC channel on Freenode and introduce yourself and start the discussion!

You need to understand something about open source licensing or package managers or code and binaries static analysis. The best way to demonstrate your capability would be to submit a small patch ahead of the project selection for an existing issue or a new issue.

Project ideas

ScanCode live scan server :

This project is to use ScanCode as a library in a web and REST API application that allows you to scan code on demand by entering a URL and then store the scan results. It could also be made available as a Travis or Github integration to scan on commit with webhooks. Bonus feature is to scan based on a received tweet of similar IRC or IM integration.

- **URLS** :
  - https://github.com/nexB/scancode-toolkit
- **Mentors** :
  - @majurg https://github.com/majurg

  - @tdruez https://github.com/tdruez

Package security vulnerability data feed (and scanner) :

The end goal for this project is to build on existing projects to match packages identified by ScanCode to existing vulnerability alerts. This is not trivial as there are several gaps in the CVE data and how they relate to packages as they are detected by ScanCode or else. This is a green field project.

The key points to tackle are:

1. create the tools to build a free and open source structured and curate security feed
   - the aggregation of packages vulnerabilities feeds in a common and structured model (CVE, distro trackers, etc),
   - the aggregation of additional security data (CWE, CPE, and more) in that model,
   - the correlation of the different data items, creating accurate relationships and matching of actual package identifiers to vulnerabilities,
   - an architecture for community curation of vulnerabilities, correlation and enhancement of the data.
2. as a side bonus, build the tools in ScanCode to match detected packages to this feed. Note there is no FOSS tool and DB that does all of this today (only proprietary solutions such as vfeed or vulndb).

- **Some Related URLS for other projects in the same realm** :

  - @majurg https://github.com/majurg
  - @JonoYang https://github.com/JonoYang
  - @pombredanne https://github.com/pombredanne

Port the Python license expression library to JScript and prepare and publish an NPM package:

Use automated code translation (for JS) for the port. Add license expression support to AboutCodeMgr with this library. As a bonus, create a web server app and API service to parse and normalize ScanCode and SPDX license expressions either in Python or JavaScript.

- **URLS** :
  - https://github.com/nexB/license-expression

  - https://github.com/bastikr/boolean.py
  - https://github.com/nexB/aboutcode-manager
  - https://github.com/jashkenas/coffeescript/wiki/list-of-languages-that-compile-to-js
- **Mentors** :
  - @JonoYang https://github.com/JonoYang
  - @majurg https://github.com/majurg

MatchCode :

Create a system for matching code using checksums and fingerprints against a repository of checksums and fingerprints. Create a basic repository for storing these fingerprints and expose a basic API. Create a client that can collect fingerprints on code and get matches using API calls to this repository or package manager APIs (Maven, Pypi, etc), or search engines APIs such as searchcode.com, debsources, or Github or Bitbucket commit hash searches/API or the SoftwareHeritage.org API.

- **URLS** :
  - https://github.com/nexB/scancode-toolkit-contrib for samecode fingerprints drafts.
  - https://github.com/nexB/scancode-toolkit for commoncode hashes
- **Mentors** :
  - @pombredanne https://github.com/pombredanne

ScanCode scan deduction :

The goal of this project is to take existing scan and match results and infer summaries and deduction at a higher level, such as the licensing of a whole directory tree.

- **URLS** :
  - https://github.com/nexB/scancode-toolkit/issues/426
  - https://github.com/nexB/scancode-toolkit/issues/377
- **Mentors** :
  - @pombredanne https://github.com/pombredanne
  - @JonoYang https://github.com/JonoYang

DeltaCode :

A new tool to help determine at a high level if the licensing for two codebases or versions of code has changed, and if so how. This is NOT a generic diff tool that identifies all codebase differences, rather it focuses on changes in licensing based on differences between ScanCode files.

- **Mentor** :
  - @majurg https://github.com/majurg

License and copyright detection benchmark :

Compare ScanCode runtimes with Fossology, licensee, LicenseFinder, license-check, ninka, slic, LiD and others. This project is to create a comprehensive test suite and a benchmark for several FOSS open source license and copyright detection engines, establish mappings between the different conventions they use for license identification and evaluate and publish the results of detection accuracy and precision.

Note that this not about the speed of scanning: the performance and time taken is accessory and a nice to have result only. What matters is the accuracy of the license detection:

1. is the right license detected and how correct is this detection?
2. when a license is detected is the correct exact text matched and returned?

So what is needed is a (large) test set of files.

Then establishing a ground truth for reference e.g. detecting then reviewing manually possibly with scancode to set up the baseline that will be used to compare all the scanners.

Then run the other tools and scancode to see how well they perform and of course establish a mapping of license identifiers: each tool may use different license ids so we need to map these to the ids used in the test baseline (e.g. the scancode license keys): all this has to be built, possibly reusing some or all of the scancode tests and lacing in all the tests from the other tools and adding more ass needed.

- **Mentors** :
  - @mjherzog https://github.com/mjherzog
  - @pombredanne https://github.com/pombredanne

Improved copyright parsing in ScanCode :

by keeping track of line numbers and offsets where copyrights are found. This would likely require either replacing or enhancing NLTK which is used as a natural language parser to add support for tracking where a copyright has been detected in a scanned text.

- **URLS** :
  - https://github.com/nexB/scancode-toolkit/tree/develop/src/cluecode
- **Mentor** :
  - @JonoYang https://github.com/JonoYang

Support full JSON and ABCD formats in AttributeCode

- **URLS** :
  - https://github.com/nexB/attributecode/issues/277
- **Mentor** :
  - @chinyeungli https://github.com/chinyeungli

Transparent archive extraction in ScanCode :

ScanCode archive extraction is currently done with a separate command line invocation. The goal of this project is to integrate archive extraction transparently into the ScanCode scan loop.

- **URLS** :
  - https://github.com/nexB/scancode-toolkit/issues/14
- **Mentor** :
  - @pombredanne https://github.com/pombredanne

Automated docker and VM images static package analysis :

to determine which packages are installed in Docker layers for RPMs, Debian or Alpine Linux. This is for the conan Docker image analysis tool.

- **URLS** :
  - https://github.com/pombredanne/conan
- **Mentor** :
  - @pombredanne https://github.com/pombredanne

Plugin architecture for ScanCode :

Create ScanCode plugins for outputs to multiple formats (CSV, JSON, SPDX, Debian Copyright)

- **URLS** :
  - https://github.com/nexB/scancode-toolkit/issues/552
  - https://github.com/nexB/scancode-toolkit/issues/381
- **Mentor** :
  - @pombredanne https://github.com/pombredanne

Static analysis of binaries for build tracing in TraceCode :

TraceCode does system call tracing. The goal of this project is to do the same using symbol, debug symbol or string matching to accomplish something similar,

- **URLS** :
  - https://github.com/nexB/tracecode-build for the existing non-static tool
  - https://github.com/nexB/scancode-toolkit-contrib for the work in progress on binaries/symbols parsers/extractors
- **Mentor** :
  - @pombredanne https://github.com/pombredanne

Better support tracing the lifecycle of file descriptors in TraceCode build :

TraceCode does system call tracing. The goal of this project is to improve the way we track open/close file descriptors in the trace to reconstruct the life of a file.

- **URLS** :
  - https://github.com/nexB/tracecode-build

- **Mentor** :
  - @pombredanne https://github.com/pombredanne

Create Debian and RPM packages for ScanCode, AttributeCode and TraceCode.

Consider also including an AppImage.org package. If you think this may not fill in a full three months project, consider also adding some extras such as submitting the packages to Debian and Fedora.

- **URLS** :
  - https://github.com/nexB/scancode-toolkit/issues/487
  - https://github.com/nexB/scancode-toolkit/issues/469
- **Mentor** :
  - @pombredanne https://github.com/pombredanne

AboutCode Manager test suite and Ci :

Create an extensive test suite for the Electron app and setup the CI to run unit, integration and smoke tests on Ci for Windows, Linux and Mac.

- **URLS** :
  - https://github.com/nexB/aboutcode-manager
- **Mentors** :
  - @jdaguil https://github.com/jdaguil
  - @pombredanne https://github.com/pombredanne

DependentCode :

Create a tool for mostly universal package dependencies resolution.

- **URLS** :
  - https://github.com/nexB/dependentcode
- **Mentors** :
  - @pombredanne https://github.com/pombredanne

FetchCode :

Create a tool for mostly universal package and code download from VCS, web, ftp, etc.

- **Mentors** :
  - @pombredanne https://github.com/pombredanne

2.2 GSoD – Google Season of Docs

Google Season of Docs is an international annual program giving technical writers an opportunity to contribute to open source projects.It fosters the open source contributions of technical writers. GSoD was started by Google in 2019. More about of GSoD - <https://developers.google.com/season-of-docs>_

2.2.1 Google Season of Docs 2021

AboutCode.org is applying to be a mentoring organization for the Google Season of Docs (GSoD) 2021.

In the event that our proposal is accepted, we'll be looking for fellow members of the FOSS community with technical writing skills and an interest in helping. If you're interested, keep reading to get a sense of what we have in mind for GSoD 2021.

Contents

AboutCode Overview

AboutCode.org is a community of developers behind a suite of Software Composition Analysis tools (command line tools, web-based and API servers and desktop applications) and data for license, origin and security:

- Where does the code come from?
- What software packages are present?
- What is its license? copyright?
- Is the code secure, maintained, well coded?
- Are there any known vulnerabilities?

All these questions are important, and are relevant to millions of free and open source software components available on the web for reuse. The answers are critical to ensure that everyone can safely consume free and open source software.

Join us to make it so!

AboutCode Projects

Our focus for GSoD 2021 is to improve documentation on our flagship projects:

- ScanCode Toolkit
- ScanCode.io
- Vulnerablecode

And specifically to create/update developement and user guides.

See *AboutCode Project Overview* for a complete list of AboutCode projects.

Technology

We use Python for programming AboutCode software. Our projects are a combination of command line tools, libraries, and web based applications based on Django and JavaScript.

Our command line tools are designed to run on Linux, macOS and Windows, and our web-based applications run only on Linux.

We write our documentation using reStructuredText with Sphinx and ReadTheDocs.

We use git and GitHub to store our code and track tasks and issues.

Technical Skills Needed

Incoming technical writers will need the following skills:

- Basic understanding of reStructuredText, Sphinx and ReadTheDocs-based documentation toolchain including git.
- Ability to understand and run programs from the command line in a terminal.
- Ability to read well-structured Python code, and to update Python docstrings.
- Ability to manage Windows and Linux based installation of our tools if need be in virtual machines.
- Ability to write technical documentation such as Tutorials, How-To Guides, and API References.

We do not expect a working knowledge of our tools as this will be picked from mentors and community guidance. An interest in FOSS licensing and software code and origin analysis would be welcome but is not a hard requirement.

Some of these skills could be picked up during the project with help from your mentors, for candidates with strong writing skills.

About Your Project Application

Check out the GSoD Tech Writer Guide and Statement Template.

Your statement of interest should be in the range of 1,000 words, and should contain the following information, plus anything else that you think is relevant:

- Personal information, i.e. Your name and contact details.
- A Project statement.
- A detailed description of your project.
- Description of your relevant skills.

- Professional information: Description of previous work, existing solutions, open-source projects, preferably with links.
- Proposed Timeline
- Proposed total budget
- Do you plan to have any other commitments during GSoD that may affect your work? Any vacations/holidays? Will you be available full time to work on your project? Please apply only if this is a serious full time commitment during the GSoD time frame.

Join the chat online or by IRC at https://gitter.im/aboutcode-org/gsod-season-of-docs. Introduce yourself and start a discussion!

An excellent, competitive way to demonstrate your capability would be to submit a documentation improvement (small changes/typos are welcome but do not demonstrate your ability to write documentation) to an AboutCode project, especially to ScanCode Toolkit, Scancode.io.

Please select a project from the list below.

Create and update scancode.io user and developer guides

- Create an HowTo guide for integrating third-party libraries into a ScanCode.io Pipeline.
- Add a tutorial for adding a new Pipeline with a third-party library.
- Extend the HowTo Guides to cover Software Composition Analysis workflows based on ScanCode.io.
- Upgrade the scancode.io Web UI documentation.
- Create an introductory video to teach how the web UI is used.
- Update and improve the existing Pipe libraries reference API documentation (which is generated from code documentation "docstrings").
- Sync the new documentation set with the code to support continuous integration with code changes.
- **Level**
  - Intermediate
- **Tech**
  - Command line processing in a Linux-compatible terminal window
  - Python [Django]
  - GitHub, reStructured Text and Sphinx
- **URLs**
  - https://scancodeio.readthedocs.io
  - https://github.com/nexB/scancode-io
  - https://gitter.im/aboutcode-org/discuss
- **Mentors**
  - https://github.com/johnmhoran
  - https://github.com/mjherzog
  - https://github.com/tdruez

  - https://github.com/AyanSinhaMahapatra

Create ScanCode-Toolkit Plugin Author Guide

The goal of this guide is to provide an end-to-end tutorial and instruction set on how to create scancode-toolkit plugins, with concrete examples and to generate a reference API documentation for modules, classes and functions used to create plugins.

Some of the specific supported activities would be:

- Explain the Plugin Architechture used in scancode-toolkit
- Explain the types of plugins used in scancode-toolkit (pre-installed/seperately-installed) and (post-scan, pre-scan, scanner)
- An exhaustive list of all plugins and what they do, with links to their code.
- How to create a minimal plugin adding some functionality to scancode-toolkit.
- Useful examples of different types of plugins
- Using nexb/skeleton as a template for plugins.

Note: Filter current scancode-toolkit GitHub Issues by Label 'documentation' to see many examples of specific areas for improvement.

- **Level**
  - Intermediate
- **Tech**
  - Some lightweight python programming to create example plugins and understand how they are constructed, the mentors will help here.
  - Command line processing in a Linux-compatible terminal window
  - GitHub, reStructured Text and Sphinx
- **URLs**
  - https://scancode-toolkit.readthedocs.io
  - https://github.com/nexB/scancode-toolkit
  - https://gitter.im/aboutcode-org/scancode
- **Mentors**
  - https://github.com/johnmhoran
  - https://github.com/majurg
  - https://github.com/AyanSinhaMahapatra

Mentoring

We have an established team of contributors that are willing to mentor the selected Tech Writers, and they have extensive experience from mentoring in the open, including a successful previous participation in Google Season of Docs 2019. We have a developed a gentle and efficient way to mentor our contributors to success.

Contact Info

Join the chat online or by IRC at https://gitter.im/aboutcode-org/gsod-season-of-docs. Introduce yourself and start the discussion!

You can also contact:

- the primary org admin directly: @pombredanne and pombredanne@gmail.com
- the GSoD coordinator directly: jmhoran@nexb.com

2.2.2 Google Season of Docs 2020

AboutCode.org is applying to be a mentoring organization for the Google Season of Docs (GSoD) 2020.

In the event that our application is accepted, we'll be looking for fellow members of the FOSS community with technical writing skills and an interest in helping. If you're interested, keep reading to get a sense of what we have in mind for GSoD 2020.

Contents

AboutCode Overview

AboutCode is a family of FOSS projects for Software Composition Analysis (SCA) and FOSS Compliance:

- Where does code come from?
- What is its license?
- What is its origin and copyright?
- Is the code secure, maintained, well coded?

All of these questions are important, and are relevant to millions of free and open source software components available on the web for reuse. The answers are critical to ensure that anyone and everyone can safely consume free and open source software.

Join us to make it so!

Our tools are used to detect and report the origin and license of source code, packages and binaries as well as to discover software and package dependencies. We are also working on projects to track security vulnerabilities, bugs and other important software package attributes.

AboutCode Projects

Our focus for GSoD 2020 is on ScanCode Toolkit and Scancode Workbench, but proposals to improve the documentation for other AboutCode projects are welcome.

See *AboutCode Project Overview* for a complete list of AboutCode projects.

Technology

We primarily use Python for AboutCode software. There is also some code in C/C++ or other languages. We use Electron/JavaScript for the ScanCode Workbench desktop application.

Our domain includes text analysis and processing (e.g., for copyright and license detection), parsing (for package manifest formats), binary analysis (to detect the origin and license of binaries), web-based tools and APIs (to expose the tools and libraries as web services) and low-level data structures for efficient matching (such as Aho-Corasick and other automata).

For documentation we primarily use reStructured Text files with Sphinx and ReadTheDocs. For command line tools we use text files for help documentation. There is still some project documentation in project wikis, but our goal is to migrate that to ReadTheDocs. For each project there will also be a README and a few other files in the corresponding GitHub repository.

Contact Info

Join the chat online or by IRC at https://gitter.im/aboutcode-org/gsod-season-of-docs. Introduce yourself and start the discussion!

You can also contact:

- the primary org admin directly: @pombredanne and pombredanne@gmail.com
- the GSoD coordinator directly: jmhoran@nexb.com

Technical Writing Skills Needed

Incoming technical writers will need the following skills:

- Ability to install and configure open source code from GitHub.
- Ability to understand and run programs from the command line in a terminal window.
- An interest in FOSS licensing and software code and origin analysis.

During the application process and during a GSoD project with us you will learn how to:

- Design and create documentation as Tutorials, HowTo Guides, Reference or Discussions.

    - See https://documentation.divio.com/introduction/ for more information about this approach.
- Create and edit documentation files in reStructured Text.
- Manage documentation files with Sphinx.
- Publish documentation to ReadTheDocs.

We are happy to help you get up to speed. The more you are able to demonstrate ability and skills in advance, the more likely we are to choose your application!

About Your Project Application

Your application should be in the range of 1,000 words, and should contain the following information, plus anything else that you think is relevant:

- Your name and contact details.
- Title of your proposal.
- Abstract of your proposal.
- Description of your idea including an explanation of what it will contribute to the project.
- Description of previous work, existing solutions, open-source projects, preferably with links.
- Details of your academic studies and any previous internships.
- Description of your relevant skills.
- Do you plan to have any other commitments during GSoD that may affect your work? Any vacations/holidays? Will you be available full time to work on your project? Please apply only if this is a serious full time commitment during the GSoD time frame.

Join the chat online or by IRC at https://gitter.im/aboutcode-org/gsod-season-of-docs. Introduce yourself and start a discussion!

An excellent, competitive way to demonstrate your capability would be to submit a documentation improvement to an AboutCode project, especially to ScanCode Toolkit or ScanCode Workbench.

You can pick a project idea from the list below. You can also submit *Your Documentation Project Ideas*.

Our Documentation Project Ideas

Note that the AboutCode focus for GSoD 2020 is on ScanCode Toolkit and ScanCode Workbench, although proposals to improve the documentation for other AboutCode projects are welcome.

Your Documentation Project Ideas are welcome too! Please chat about them to increase your chances of success!

Improve ScanCode Toolkit (SCTK) Documentation

- Upgrade the ScanCode Toolkit documentation on ReadTheDocs by streamlining and re-organizing it.
- Apply the Tutorial, HowTo, Reference and Discussions framework (or propose alternative).
- Implement process to sync documentation changes with releases.

Note: Filter current SCTK GitHub Issues by Label 'documentation' to see many examples of specific areas for improvement.

- **Level**
  - Intermediate
- **Tech**
  - Command line processing in a Linux-compatible terminal window
  - GitHub, reStructured Text and Sphinx
- **URLs**
  - https://scancode-toolkit.readthedocs.io/en/latest/index.html
  - https://github.com/nexB/scancode-toolkit
  - https://gitter.im/aboutcode-org/scancode
- **Mentors**
  - https://github.com/johnmhoran
  - https://github.com/mjherzog

Improve ScanCode Workbench (SCWB) Documentation

- Upgrade the ScanCode Workbench documentation on ReadTheDocs with a focus on Tutorials and HowTo Guides because this is a GUI application.
- Apply the Tutorial, HowTo, Reference and Discussions framework (or propose alternative).
- Implement process to sync documentation changes with releases.

Note: Filter current SCWB GitHub Issues by Label 'documentation' to see many examples of specific areas for improvement.

- **Level**
  - Intermediate
- **Tech**
  - GUI design
  - GitHub, reStructured Text and Sphinx
- **URLs**
  - https://scancode-workbench.readthedocs.io/en/latest/index.html
  - https://github.com/nexB/scancode-workbench
  - https://gitter.im/aboutcode-org/scancode-workbench
- **Mentors**
  - https://github.com/johnmhoran
  - https://github.com/majurg

Automate Code Documentation

- Identify tools to generate code documentation from Python files.

- Define coding standards necessary to support automated generation of code documentation across AboutCode projects.
- Implement process and tools to automate publication of code documentation for ScanCode Toolkit to ReadTheDocs using Sphinx and related extensions.
- **Level**
  - Intermediate
- **Tech**
  - Python programming
  - GitHub, reStructured Text and Sphinx
- **URLs**
  - https://scancode-workbench.readthedocs.io/en/latest/index.html
  - https://github.com/nexB/scancode-workbench
  - https://gitter.im/aboutcode-org/scancode-workbench
- **Mentors**
  - https://github.com/johnmhoran
  - https://github.com/majurg

Your Documentation Project Ideas

Download and install ScanCode Toolkit and Scancode Workbench and try them out. For example, you may try scanning an open source software package in a technology with which you are familiar. What are the documentation weak points?

- Is it difficult to get started? A **Tutorial** documentation opportunity.
- Is it difficult to accomplish a specific objective? A **How-To** documentation opportunity.
- Are the capabilities of the tool too mysterious? Do you want to know more about what you can do with it? A **Reference** documentation opportunity.
- Do you feel that you need to understand its concepts better in order to use it and trust it? Do you want to know more about how the code scanning actually works? A **Discussion** documentation opportunity.

Feel free to propose and describe your own documentation ideas.

Mentoring

We welcome new mentors to help with the program. We require some understanding of the project domain to join as a mentor. Contact the team on Gitter at https://gitter.im/aboutcode-org/gsod-season-of-docs

2.2.3 Google Season of Docs 2019 Report

Project Name

The Project Name was **"Reference for Command Line Options in scancode-toolkit and Reorganize the structure of AboutCode documentation at aboutcode.readthedocs.io"**

About Me

Name - Ayan Sinha Mahapatra
Email : ayansmahapatra@gmail.com
Country : India
Links :

- Github
- Twitter
- Website
- Resume

Important Links for this GSoD Project

- GSoD Report
- GSoD Proposal
- ScanCode Toolkit Docs
- Aboutcode Docs

Project Overview

1. **Restructured Documentation hosted at ReadTheDocs:** Outdated Documentation from GitHub Wikis was updated, improved and converted to .RST, to be hosted at aboutcode.readthedocs.io.
2. **Documentation Tests and Roadmaps:** Documentation tests were added to check Documentation Builds, Internal/External Links, and Style Standards. These tests were added in both aboutcode and scancode-toolkit and already existing/new documentation was made compliant of these tests.
3. **Command Line Options Referance:** The entire Command Line Options were listed, explained, and their application elaborated from scratch. This is the main goal and the most important addition to the scancode-toolkit documentation.
4. **Migration of Scancode-Toolkit docs into its own Repository:** After adding the scancode toolkit docs to aboutcode and reviews, this section was migrated to its own repository, to be distributed with scancode-toolkit and with local builds enabled.
5. **[WIP] Improve/Add to Existing Tutorials/How-Tos:** Added two major Tutorials and other Tutorials/How-Tos were also updated to be consistent with the latest scancode versions and more Tutorials/How-Tos can be added later to better help the users.
6. **[WIP] Add Plugin Support:** A cookiecutter based plugin creation system has to be added, and relevant docs for this process and for the plugin architecture has to be added.
7. **[WIP] Solve Other Documentation Issues:** Solving multiple issues listed under the tag “Documentation”.

Pull Requests

PRs before GSoD Started @ nexB/aboutcode

- [#17] Adds Travis-CI for sphinx-build and linkcheck
- [#15] Adds Documentation from Wiki
- [#13] Adds GitHub wiki of Scancode-Toolkit and Scancode-Workbench

GSoD PRs @ nexB/scancode-toolkit

- [#1784] Add Travis CI Test For Docs
- [#1827] Add New Issue and Pull Request Templates
- [#1812] Add Documentation from Aboutcode
- [WIP] Add Cookiecutter Plugin and Plugin Docs
- [WIP] [#1847] Fix remaining documentation Issues

GSoD PRs @ nexB/aboutcode

- [#26] Adds Documentation Versioning, Command Line Options, Changelog
- [#27] CLI Options Reference for v3.1.1
- [#29] Update Docs with changes in Wiki
- [#30] Add doc8 style checks to Travis-CI
- [#31] Fix template error
- [#33] Add final Changes/Improvements before Migrating
- [#34] Delete scancode-toolkit documentation
- [#35] Add GSoD 2019 Report

Acknowledgments

I would like to thank Dennis Clark, Philippe Ombredanne and Steven Esser for their help throughout my GSoD project, from helping me prepare my proposal and project to constructive criticism, nit-picky reviews, conference calls to discuss project roadmaps and to explain to me when I was stuck in any problem. Their support and positivity helped me through this project and made me enjoy every bit of it.

2.2.4 Google Season of Docs 2019

AboutCode has been accepted as a participant in the Google Season of Documents in 2019 as a mentoring org, and is looking for people with technical writing skills. This page contains information for technical writers and anyone else interested in helping.

AboutCode is a family of FOSS projects to uncover data about software code:

- Where does the code come from? which software package?

- What is its license? copyright?
- Is the code secure, maintained, well coded?

All these questions are important, and are relevant to millions of free and open source software components available on the web for reuse. The answers are critical to ensure that everyone can safely consume free and open source software.

Join us to make it so!

Our tools are used to help detect and report the origin and license of source code, packages and binaries as well as to discover software and package dependencies, and in the future track security vulnerabilities, bugs and other important software package attributes. This is a suite of command line tools, web-based and API servers and desktop applications.

Table of Contents

List of AboutCode projects

Note that the AboutCode focus for GSOD 2019 is on **ScanCode Toolkit** and **ScanCode Workbench**, although proposals to improve the documents of other AboutCode projects are welcome.

- ScanCode Toolkit is a popular command line tool to scan code for licenses, copyrights and packages, used by many organizations and FOSS projects, small and large.
- Scancode Workbench (formerly AboutCode Manager) is a JavaScript, Electron-based desktop application to review scan results and document your origin and license conclusions.
- Other AboutCode projects are described at https://www.aboutcode.org and https://github.com/nexB/aboutcode

  We also work closely with, contribute to and have co-started several other orgs and projects:

- Package URL is an emerging standard to reference software packages of all types with simple, readable and concise URLs.
- SPDX is the Software Package Data Exchange, a specification to document the origin and licensing of software packages.
- ClearlyDefined is a project to review FOSS software and help FOSS projects to improve their licensing and documentation clarity.

Contact

Join the chat online or by IRC at https://gitter.im/aboutcode-org/discuss Introduce yourself and start the discussion!

For personal issues, you can contact the primary org admin directly: @pombredanne and pombredanne@gmail.com

or the GSOD coordinator directly at dmclark@nexb.com

Please ask questions the smart way: http://www.catb.org/~esr/faqs/smart-questions.html

Technology

We primarily use Python (and some C/C++) for code analysis. We use Electron/JavaScript for GUI.

Our domain includes text analysis and processing (for instance for copyright and license detection), parsing (for package manifest formats), binary analysis (to detect the origin and license of binaries, which source code they come from, etc.) as well as web based tools and APIs (to expose the tools and libraries as web services) and low-level data structures for efficient matching (such as Aho-Corasick and other automata).

Our documentation is provided in text files that support the help function of our command line tools. We also have begun to provide documentation in the Wiki section of some AboutCode projects.

Technical Writing Skills Needed

Incoming technical writers will need the following skills:

- Ability to install and configure open source code from GitHub.
- Ability to understand and run programs from the command line in a terminal window.
- Familiarity with the four document functions described at https://www.divio.com/blog/documentation/
- Ability to create and edit wiki pages with multiple markdown languages.
- An interest in FOSS licensing and software code and origin analysis.

We are happy to help you get up to speed, and the more you are able to demonstrate ability and skills in advance, the more likely we are to choose your application!

About your project application

Your application should be in the range of 1000 words, and should contain the following information, plus anything else that you think is relevant:

- Your name and contact details
- Title of your proposal
- Abstract of your proposal

- Description of your idea including an explanation of what it will contribute to the project, such as the software development life cycle requirements that you expect to help with the documentation improvements.
- Description of previous work, existing solutions, open-source projects, preferably with links.
- Details of your academic studies and any previous internships.
- Descriptions of your relevant skills.
- Do you plan to have any other commitments during GSOD that may affect your work? Any vacations/holidays? Will you be available full time to work on your project? Please apply only if this is a serious full time commitment during the GSOD time frame.

Join the chat online or by IRC at https://gitter.im/aboutcode-org/discuss Introduce yourself and start the discussion!

An excellent, competitive way to demonstrate your capability would be to submit a documentation improvement to an AboutCode project, especially to ScanCode Toolkit or ScanCode Workbench.

You can pick any project idea from the list below. You can also submit *Your Documentation Project ideas*.

Our Documentation Project ideas

Here is a list of candidate project ideas for your consideration, organized by documentation function: **Tutorial** , **How-To** , **Reference** , **Discussion**.

Note that the AboutCode focus for GSOD 2019 is on ScanCode Toolkit and ScanCode Workbench, although proposals to improve the documents of other AboutCode projects are welcome.

Your Documentation Project ideas are welcome too! Please chat about them to increase your chances of success!

Tutorial ideas

Scan a Codebase and Analyze the Results

Provide specific instructions to guide a new user to:

- Scan a somewhat complex sample codebase using scancode-toolkit.
- Import the results into ScanCode Workbench.
- Analyze the scan results.
  - **Level**
    - Intermediate
  - **Tech**
    - Command line processing in a Linux-compatible terminal window
  - **URLS**
    - https://github.com/nexB/scancode-toolkit/blob/develop/README.rst
    - https://github.com/nexB/scancode-toolkit/wiki
    - https://github.com/nexB/scancode-workbench/blob/develop/README.md
    - https://github.com/nexB/scancode-workbench/wiki
  - **Mentors**
    - https://github.com/DennisClark

How-To ideas

How To Get the License Clarity Score of a Package

Explain the recommended scancode-toolkit options to get a license clarity score.

- **Level**
  - Intermediate
- **Tech**
  - Command line processing in a Linux-compatible terminal window
- **URLS**
  - https://github.com/nexB/scancode-toolkit/blob/develop/README.rst
  - https://github.com/nexB/scancode-toolkit/wiki
  - https://github.com/nexB/scancode-workbench/blob/develop/README.md
  - https://github.com/nexB/scancode-workbench/wiki
- **Mentors**
  - https://github.com/DennisClark

How To Discover Licensing Issues in a Software Project

- Explain the recommended scancode-toolkit options to discover licenses.
- Explain how to take advantage of license policy support.
  - **Level**
    - Intermediate
  - **Tech**
    - Command line processing in a Linux-compatible terminal window
  - **URLS**
    - https://github.com/nexB/scancode-toolkit/blob/develop/README.rst

    - https://github.com/nexB/scancode-workbench/wiki
  - **Mentors**
    - https://github.com/DennisClark

Reference ideas

ScanCode Output Formats

Explain the various ScanCode output formats and their business purposes.

- **Level**

    - Intermediate
- **Tech**
    - Command line processing in a Linux-compatible terminal window
- **URLS**
    - https://github.com/nexB/scancode-toolkit/blob/develop/README.rst
    - https://github.com/nexB/scancode-toolkit/wiki
    - https://github.com/nexB/scancode-workbench/blob/develop/README.md
    - https://github.com/nexB/scancode-workbench/wiki
- **Mentors**
    - https://github.com/DennisClark

Discussion ideas

Integrating ScanCode into a Software Development Lifecycle

Discuss options and techniques to integrate ScanCode into a software development lifecycle workflow:

- During software creation and maintenance.
- During software check-out/check-in.
- During sofware build and test.
    - **Level**
        * Intermediate
    - **Tech**
        * Command line processing in a Linux-compatible terminal window
    - **URLS**
        * https://github.com/nexB/scancode-toolkit/blob/develop/README.rst
        * https://github.com/nexB/scancode-toolkit/wiki
        * https://github.com/nexB/scancode-workbench/blob/develop/README.md
        * https://github.com/nexB/scancode-workbench/wiki
    - **Mentors**
        * https://github.com/DennisClark

Your Documentation Project ideas

Download and install ScanCode Toolkit and ScanCode Workbench and try them out. For example, you may try scanning an open source software package in a technology with which you are familiar. What are the documentation weak points?

- Is it difficult to get started? A **Tutorial** document opportunity.
- Is it difficult to accomplish a specific objective? A **How-To** document opportunity.

- Are the capabilities of the tool too mysterious? Do you want to know more about what you can do with it? A **Reference** document opportunity.
- Do you feel that you need to understand its concepts better in order to use it and trust it? Do you want to know more about how the code scanning actually works? A **Discussion** document opportunity.

Feel free to propose and describe your own documentation ideas.

Mentoring

We welcome new mentors to help with the program. We require some understanding of the project domain to join as a mentor. Contact the team on Gitter at https://gitter.im/aboutcode-org/discuss

2.3 Contributor Project Ideas (old)

2.3.1 Welcome to AboutCode!

AboutCode is a project to uncover data ... about software code:

- where does the code come from? which software package?
- what's is its license? copyright?
- is the code secure, maintained, well coded?

All these are questions that are important to find answers to: there are million of free and open source software components available on the web.

Knowing where a software package comes from, if it is vulnerable and what's its licensing should be a problem of the past such that everyone can safely consume more free and open source software.

Join us to make it so!

Our tools are used to help detect and report the origin and license of source code, packages and binaries as well as discover software and package dependencies, and track security vulnerabilities, bugs and other important software package attributes. This is a suite of command line tools, web-based and API servers and desktop applications.

2.3.2 Table of Contents

  - *License and copyright detection benchmark*
  - *Improved copyright parsing and speed in ScanCode*
  - *Transparent archive extraction in ScanCode*
  - *Port ScanCode to Python 3*
  - *Automated Docker, containers and VM images static package analysis*
  - *Static analysis of binaries for build tracing in TraceCode*
  - *Create Linux distro packages for ScanCode*
  - *Package URL implementations in many programming languages*
  - *DependentCode: a mostly universal Package dependencies resolver*

2.3.3 AboutCode projects are. . .

- **ScanCode Toolkit** a popular command line tool to scan code for licenses, copyrights and packages, used by many organizations and FOSS projects, small and large.
- **AboutCode Manager** a JavaScript, Electron-based desktop application to review scan results and document your conclusions
- **AboutCode Toolkit** a set of command line tools to document and inventory known packages and licenses and generate attribution docs
- TraceCode Toolkit: a set of command line tools to find which source code is used to create a compiled binary
- DeltaCode Toolkit: a new command line tool to compare codebases based on scan and determine if and where there are material differences that affect licensing
- VulnerableCode Server: a new server-side application to track package vulnerabilities
- AboutCode Server: a new server-side application to run and organize scans and ABC data (formerly ScanCode server)
- ConAn: a command line tool to analyze the code in Docker and container images
- license-expression: a library to parse and render boolean license expression (such as SPDX)
- Other new tools for source and binary code matching/search and package inventories.

We also work closely with other orgs and projects:

- purl aka. Package URLs https://github.com/package-url which is an emerging standard to reference software packages of all types.
- SPDX.org aka. Software Package Data Exchange, a spec to document the origin and licensing of packages

2.3.4 Contact

Join the chat online or by IRC at https://gitter.im/aboutcode-org/discuss introduce yourself and start the discussion!

For personal issues, you can contact the primary org admin directly: @pombredanne and pombredanne@gmail.com

Please ask questions the smart way: http://www.catb.org/~esr/faqs/smart-questions.html

2.3.5 Technology

Discovering the origin of code is a vast topic. We primarily use Python for this and some C/C++ (and eventually Rust) for performance sensitive code and Electron/JavaScript for GUI. We are open to using any other language within reason.

Our domain includes text analysis and processing (for instance for copyrights and licenses), parsing (for package manifest formats), binary analysis (to detect the origin and license of binaries, which source code they come from, etc) as well as web based tools and APIs (to expose the tools and libraries as web services) and low-level data structures for efficient matching (such as Aho- Corasick and other automata)

2.3.6 About your project application

We expect your application to be in the range of 1000 words. Anything less than that will probably not contain enough information for us to determine whether you are the right person for the job. Your proposal should contain at least the following information, plus anything you think is relevant:

- Your name
- Title of your proposal
- Abstract of your proposal
- Detailed description of your idea including explanation on why is it innovative and what it will contribute
- hint: explain your data structures and the main processing flows in details.
- Description of previous work, existing solutions (links to prototypes, bibliography are more than welcome)
- Mention the details of your academic studies, any previous work, internships
- Relevant skills that will help you to achieve the goal (programming languages, frameworks)?
- Any previous open-source projects (or even previous GSoC) you have contributed to and links.
- Do you plan to have any other commitments during GSoC that may affect your work? Any vacations/holidays? Will you be available full time to work on your project? (Hint: do not bother applying if this is not a serious full time commitment)

Join the chat online or by IRC at https://gitter.im/aboutcode-org/discuss introduce yourself and start the discussion!

You need to understand something about open source licensing or package managers or code and binaries static analysis or low level data structures. The best way to demonstrate your capability would be to submit a small patch ahead of the project selection for an existing issue or a new issue.

We will **always** consider and prefer a project submissions where you have submitted a patch over any otherr submission without a patch.

2.3.7 Our Project ideas

Here is a list of candidate project ideas for your consideration. Your own ideas are welcomed too! Please chat about them to increase your chances of success!

Note that there is NO specific order in this list!

AboutCode data server

This project is to futher and evolve the ScanCode server (was started last year as a 2017 GSoC project) and rename it as the AboutCode server.

The features of this updated server would be:

- Store any ABC data including ScanCode scans See *AboutCode Data : ABCD*
- Organize the data in projects (including possibly user-private projects)
- Execute selectively AboutCode tools such as ScanCode-toolkit, AboutCode-toolkit, etc.
- Integrate the storage and retrieval of scans and ABC data with the AboutCode Manager app through the JSON API.
- Add a Github integration to scan/run an ABC tool on commit with webhooks.
  - Bonus feature is to scan based on a received tweet of similar IRC or IM integration.
- **Tech**
  - Python 2, Django, PostgreSQL, DRF, JavaScript, Electron

VulnerableCode Package security vulnerability data feed (and scanner)

This project is to futher and evolve the VulnerableCode server and and software package vulnerabilities data aggregator.

VulnerableCode was started last year as a 2017 GSoC project. Its goal is to collect and aggregate vulnerabilities data and provide semi-automatic correlation. In the end it should provide the basis to report vulnerabilities alerts found in packages identified by ScanCode.

This is not trivial as there are several gaps in the CVE data and how they relate to packages as they are detected by ScanCode or else.

The features and TODO for this updated server would be:

- Aggregate more and new packages vulnerabilities feeds,
- Automating correlation: add smart relationship detection to infer new relatiosnhips between available packages and vulnerabilities from mining the graph of existing relations.
- Create a ScanCode plugin to report vulnerabilities with detected packages using this data.
- Integrate API lookup on the server withe the AboutCode Manager UI
- Create a UI and model for community curation of vulnerability to package mappings, correlations and enhancements.

- **Tech**

  - @pombredanne https://github.com/pombredanne

Integrate the license expression library in ScanCode (Python) and AboutCode Manager (JScript)

In GSoC 2017, this Python library was ported to JavaScript using Transcrypt.

The goal of this project is to add support for license expressions in multiple projects and evolve the license expression library as needed:

- in Python:
  - the SPDX Python library
  - the ScanCode toolkit. This also include the proper detection of license expressions in SPDX-License-Identifier tags.
  - the AboutCode toolkit
- in JavaScript:
  - the AboutCode Manager
- in both languages in the core license expression proper, add support for a built-in mode for strict SPDX expressions
- **Tech**

High volume matching automatons and data structures

MatchCode will provide ways to efficiently match actual code against a large stored indexes of open source code.

To enable this, we need to research and create efficient and compact data structures that are specialized for the type of data we lookup. Given the volume to consider (typically multi billion values indexed) there are special considerations to have compact and memory efficient dedicated structures (rather than using a general purpose DB or Key/value pair store) that includes looking at automata, and memory mapping. This types of data structures should be implemented in Rust as a preference (though C/C++ is OK) and include Python bindings.

There are several areas to research and implement:

- A data structure to match efficiently a batch of fix-width checksums (e.g. SHA1) against a large index of such checksums, where each checksum points to one or more files or packages. A possible direction is to use finite state transducers or specialized B-tree indexes. Since when a codebase is being matched there can be millions of lokkups to do, the batch matching is preferred.
- A data structure to match efficiently a batch of fix-width byte strings (e.g. LSH) against a large index of such LSH within a fixed hamming distance, where each points to one or more files or packages. A possible direction is to use finite state transducers (possibly weighted), specialized B-tree indexes or multiple hash-like on-disk tables.
- A memory-mapped Aho-Corasick automaton to build large batch tree matchers. Available Aho-Corasick automaton may not have a Python binding or may not allow memory-mapping (like pyahocorasick we use in ScanCode). The volume of files we want to handle requires to reuse, extend or create aspecialized tree/paths matching automatons that can handle eventually billions of nodes and are larger than the available RAM. A possible direction is to use finite state transducers (possibly weighted).
- Feature hashing research: we deal with manyt "features" and hashing to limit the number and size of the each features seems to be a valuable thing. The goal is to research feature hashing with short hashes (15, 16 and 32 bits) and evaluate if this leads to acceptable fasle-positive and loss of accuracy in the context of the data structures mentioned above.

Then using these data structures, the project should create a system for matching code as a Python-based server exposing a simple API. This is a green field project.

- **Tech**
  - Rust, Python

  - @JonoYang https://github.com/JonoYang

License and copyright detection benchmark

Compare ScanCode runtimes with Fossology, licensee, LicenseFinder, license- check, ninka, slic, LiD and others. This project is to create a comprehensive test suite and a benchmark for several FOSS open source license and copyright detection engines, establish mappings between the different conventions they use for license identification and evaluate and publish the results of detection accuracy and precision.

Note that this not only about the speed of scanning: the performance and time taken is accessory and a nice to have as a result. What matters is benchmarking the accuracy of the license detection:

1. is the right license detected and how correct is this detection?
2. when a license is detected is the correct exact text matched and returned?

So what is needed is a (large) test set of files.

Then establishing a ground truth for reference e.g. detecting then reviewing manually possibly with ScanCode to set up the baseline that will be used to compare all the scanners.

Then run the other tools and ScaCode to see how well they perform and of course establish a mapping of license identifiers: each tool may use different license ids so we need to map these to the ids used in the test baseline (e.g. the scancode license keys): all this has to be built, possibly reusing some or all of the scancode tests and lacing in all the tests from the other tools and adding more as needed.

- **Tech**
  - Python

  - @pombredanne https://github.com/pombredanne

Improved copyright parsing and speed in ScanCode

Copyright detection is the slowest scanner in ScanCode. It is based on NLTK part of speech tagging and a copyright grammar.

The goal of this project is to refactor Copyright detection for speed and simplicity possibly implementaing a new parser (PEG?, etc) or reimplementing core elements in Rust with a Python binding.

This would include also keeping track of line numbers and offsets where copyrights are found.

This would likely require either replacing or enhancing NLTK which is used as a natural language parser.

  - Python, Rust
- **URLS**
  - https://github.com/nexB/scancode-toolkit/tree/develop/src/cluecode
- **Mentor**
  - @JonoYang https://github.com/JonoYang

Transparent archive extraction in ScanCode

ScanCode archive extraction is currently done with a separate command line invocation. The goal of this project is to integrate archive extraction transparently into the ScanCode scan loop. This would be using the new plugins architecture.

- **Tech**
  - Python
- **URLS**
  - https://github.com/nexB/scancode-toolkit/issues/14
- **Mentor**
  - @pombredanne https://github.com/pombredanne

Port ScanCode to Python 3

ScanCode runs only on Python 2.7 today. The goal of this project is to port ScanCode to support both Python 2 and Python 3.

- **Tech**
  - Python
- **URLS**
  - https://github.com/nexB/scancode-toolkit/issues/295
- **Mentor**
  - @pombredanne https://github.com/pombredanne

Automated Docker, containers and VM images static package analysis

The goal of this project is to further the Conan container static analysis tool to effectively support proper inventory of installed packages without running the containers.

This includes determining which packages are installed in Docker layers for RPMs, Debian or Alpine Linux. And this woudl eventually require the integration of ScanCode.

- **Tech**
  - Python, Go?
- **URLS**
  - https://github.com/pombredanne/conan

- **Mentor**
  - @pombredanne https://github.com/pombredanne

Static analysis of binaries for build tracing in TraceCode

TraceCode does system call tracing only today.

- The primary goal of this project is to do the same using symbol, debug symbol or string matching to accomplish something similar using static analysis.
- This project also would cover updating TraceCode to use the Click comamnd line toolkit (like for ScanCode).
- Finally thsi project should improve the tracing of the lifecycle of file descriptors in TraceCode build. We need to improve how TraceCode does system call tracing by improving the way we track open/close file descriptors in the trace to reconstruct the lifecycle of a traced file.
- **Tech**
  - Python, Linux
- **URLS**
  - https://github.com/nexB/tracecode-toolkit for the existing non-static tool
  - https://github.com/nexB/scancode-toolkit-contrib for the work in progress on binaries/symbols parsers/extractors
- **Mentor**
  - @pombredanne https://github.com/pombredanne

Create Linux distro packages for ScanCode

The goal of this project is to ensure that we have proper packages for Linux distros for ScanCode.

The first step is to debundle pre-built binaries that exist in ScanCode such that they come either from system-packages or pre-built Python wheels. This covers libarchive, libmagic and a few other native libraries.

The next step is to ensure that all the dependencies from ScanCode are also available as distro packages.

The last step is to create proper distro packages for RPM, Debian, Nix and GUIX, Alpine, Arch and Gentoo and also an AppImage.org package as well as a proper Docker image and eventually submit these package to the distros.

As a bonus, the same could then be done for AboutCode toolkit and TraceCode.

This requires a good understanding of packaging and Python.
